OVERVIEW

Deployed medical providers at all roles of care must be prepared to recognize and manage Acute Coronary Syndrome (ACS). Under optimal conditions, treatment is initiated with medical therapy and may be followed by prompt coronary angiography and revascularization. Emergent percutaneous coronary intervention (PCI) is not available in most deployed locations however, and the time for such intervention is often dependent on long-range evacuation. This CPG provides guidance on best management for ACS patients in the deployed and resource constrained environment.

BACKGROUND

Coronary heart disease (CHD) is the leading cause of mortality in the U.S. and worldwide.[1,2] Cardiovascular health may in fact be worse for active duty servicemen when compared to the civilian population.[3] Additionally, cardiovascular disease is the second most common chronic disease among active duty Army personnel following arthritis.[4] While clinical CHD typically presents at older ages, significant coronary atherosclerosis and myocardial infarction can manifest in young adults and teenage patients.[5] In a cross-sectional study by Webber et al, coronary atherosclerosis was identified in 8.5% of the autopsies performed on U.S. military personnel in Operation Iraqi Freedom/Operation New Dawn (OIF/OND) and Operation Enduring Freedom (OEF).[6] In this study population, older age, lower educational level, higher body max index at military entrance, and a prior diagnoses of: dyslipidemia, hypertension, and obesity, were associated with a higher prevalence of atherosclerosis. Additionally, myocardial infarction (MI)/ACS was the most common medical/non-surgical diagnosis for Critical Care Air Transport Team (CCATT) evacuations, representing 6.6% of 290 patients evacuated by CCATT during OIF/OEF.[7]

Acute coronary syndrome is typically a consequence of CHD and refers to a spectrum of disease among patients experiencing, or suspected of experiencing, myocardial ischemia.[8] ACS is further divided into three subgroups: 1) ST elevation myocardial infarction (STEMI), 2) non-ST elevation myocardial infarction (NSTEMI), and 3) unstable angina.

When evaluating patients with chest pain concerning ACS, it is important to consider other life-threatening causes of chest pain such as pulmonary emboli, pneumonia, aortic dissection, pneumothorax, esophageal rupture, and myocarditis as they are managed differently. A thorough history and physical exam may be helpful in guiding the deployed provider towards a presumptive diagnosis. When available, imaging, labs, and electrocardiogram (ECG) can further assist in differentiating the etiology of chest pain.[9,10]

Diagnosis and management of ACS can be uniquely challenging in locations where PCI centers or treatment with fibrinolytics are not available. PCI is recommended within 120 minutes of first medical contact and is the preferred and most common treatment for ACS in the U.S..[11] However, if evacuation is required, the delay to reach a PCI center may exceed the recommended door-to-balloon time. Military physicians located Outside Continental United States (OCONUS) may therefore be required to treat ACS with fibrinolytics, which is not common in most U.S. locations. Additionally, many diagnostic tools helpful in evaluating chest pain, such as ECGs and cardiac troponin assays, may not be available in many deployed locations. Refer to Appendix C for ACS management recommendations by role of care.

It is the responsibility of every medical provider to be prepared for initial management of ACS, to include understanding how to use teleconference services. Diagnosis and treatment of ACS should be guided by expert consultation. In addition, the capability to obtain and transmit an ECG and to provide cardiac first aid treatments with oxygen, nitroglycerin and aspirin are key capabilities in initial stabilization and should be available to all deployed medical providers. Expanded capabilities for medical stabilization with anti-platelet agents, systemic anticoagulation and fibrinolytic therapy should be available in the evacuation chain within 24 hours, and must be considered during operational planning. Fibrinolytics are ideally given within 12 hours of symptom onset; however there may be a benefit up to 24 hours after symptom onset.[12,13]

DIAGNOSIS

ACS is a clinical syndrome that includes MI and unstable angina. An MI can present as either a STEMI or NSTEMI. A STEMI typically occurs as a result of plaque rupture and subsequent thrombosis of a coronary artery that leads to infarction and subsequent ECG changes. An NSTEMI does not have the ECG changes seen in STEMI but can also occur secondary to plaque rupture (Type 1 NSTEMI) or to inadequate blood flow to meet the metabolic demands of the myocardium in conditions like sepsis, pulmonary embolism, or coronary vasospasm (Type 2 NSTEMI). In either case, both STEMI and NSTEMI will result in an elevated troponin. Unstable angina is characterized by new onset chest pain, pain lasting greater than 20 minutes or pain at rest or with minimal exertion. While unstable angina can occur with ECG changes not diagnostic of STEMI, it does not have elevated troponins.[10] It is essential to differentiate between STEMI and NSTEMI since those with STEMI require emergent coronary intervention.[9] NSTEMI is more common than STEMI, representing 60-70% of myocardial infarctions.[14] NSTEMI with coronary occlusion is present in 25% of cases.[15]

ACS pain is classically described as exertional, pressure-like chest pain with radiation to the jaw, neck, one or both arms/shoulders, or back. Associated symptoms include nausea/vomiting, shortness of breath, and diaphoresis.[10] Atypical symptoms (dyspnea alone, fatigue, weakness, epigastric pain, palpitations, syncope, nausea alone, and cardiac arrest) are more common in the elderly, women, and diabetics. Atypical symptoms are presented symptoms in one-third of confirmed myocardial infarctions.[16]

Troponin is a protein released from myocardial tissue and is indicative of cardiac cell death. Serum troponin levels begin to rise measurably as early as 2 to 3 hours after onset and can remain elevated for up to 7 days.[10] When available, cardiac troponin assays (cardiac specific I or T) should be used in the diagnosis of MI. A troponin value above the 99th percentile upper reference limit (determined by the assay type) is considered positive. Troponin values may continue to rise, or they may decline depending on the timing of the clinical event, and both situations should raise concern for ACS.[10,17] Due to the time elapsed between cardiac cell death and laboratory detectable rise in troponin levels, the troponin level may be checked serially, usually every 3 to 6 hours.[18]

The following are clinical findings in combination with a rise and/or fall in troponin values that constitute the diagnosis of acute MI:[19]

- Symptoms of ischemia (See above paragraph.)
- New ischemic ECG changes
- Development of pathological Q waves

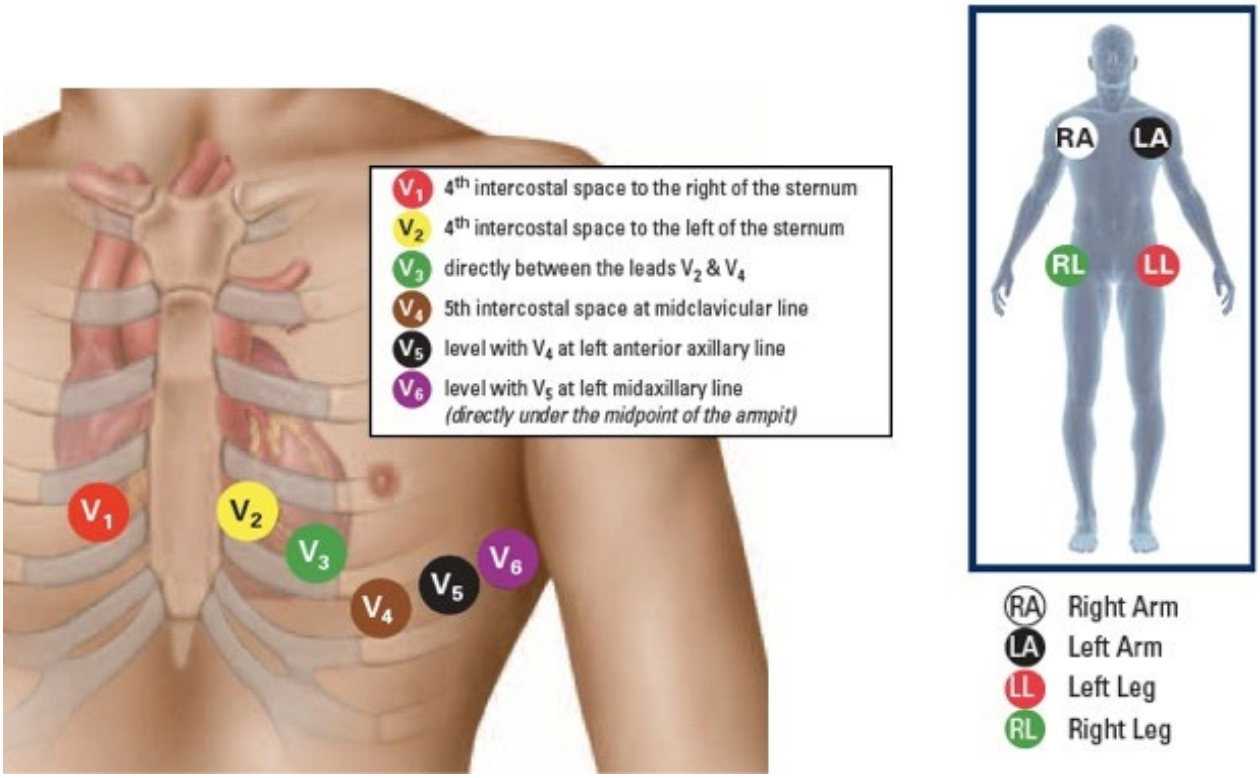
- Imaging evidence of new loss of viable myocardium or new regional wall motion abnormality
- Identification of an intra-coronary thrombus on angiography or autopsy

Other clinical conditions may present with elevated troponin. Some of these conditions may manifest symptoms similar to ACS (myocarditis, pulmonary embolism, and aortic dissection), while other conditions may present without features of ACS (such as rhabdomyolysis, sepsis and renal failure) and their management is distinct from that of ACS.[19] It is therefore important to consider the clinical manifestations and additional studies (ECG, echocardiography) in addition to troponin in the diagnosis of ACS. Keep in mind that in forward deployed locations, laboratory testing for troponin may not be available, and a high index of suspicion must be maintained in the presence of appropriate symptoms.

DIAGNOSIS OF ACS BY ECG CHARACTERISTICS

The 12-lead ECG of STEMI follows an anatomical distribution based on the infarcted artery. ST-elevation in one region should manifest with reciprocal ST-depression in the opposite anatomic region. ST-elevation must be present in two contiguous leads to be diagnostic. Figure 1 shows proper ECG lead placement for a typical 12-lead ECG.

Figure 1. Correct 12-Lead ECG Placement[20]



In conjunction with symptoms consistent with myocardial ischemia, the following are the ECG criteria diagnostics of STEMI:[19]

- New ST-elevations ≥ 0.1 mV in 2 or more contiguous leads except V_2-V_3
- New ST-elevations in V_2-V_3 with the below criteria:
  - ≥ 0.25 mV in men aged < 40 years
  - ≥ 0.2 mV in men aged ≥ 40 years
  - ≥ 0.15 mV in women

Figures 2 - 4 demonstrate typical patterns of anterior, inferior, and lateral wall STEMI, respectively.

Figure 2. 12-Lead ECG Evidence of Anterior STEMI. Notice the ST-elevations in leads I, aVL, and V_1-V_6 with reciprocal ST-depressions in the inferior leads (III and aVF)[21]

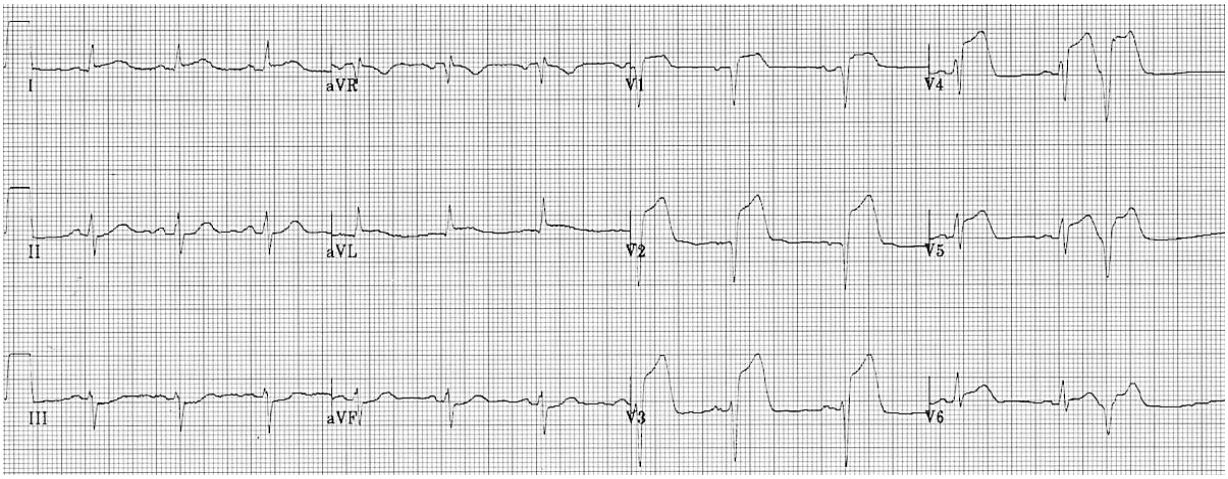


Figure 3. 12-Lead ECG of Inferior STEMI. Notice the ST-elevations in leads II, III, and aVF with reciprocal ST-depressions in antero-lateral leads (I, aVL,V_2, V_3 and V_4)[22]

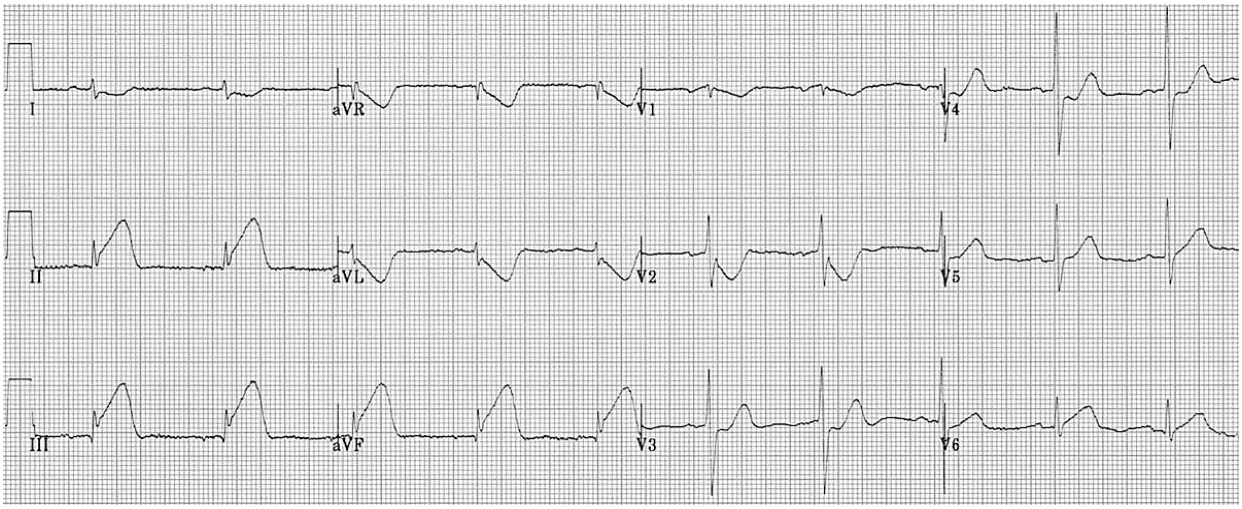

Figure 4. 12-Lead ECG of Lateral STEMI. Notice the ST-elevations in leads I, aVL, V_5, and V_6 with reciprocal ST-depressions in the inferior leads (II, III, and aVF) [23]

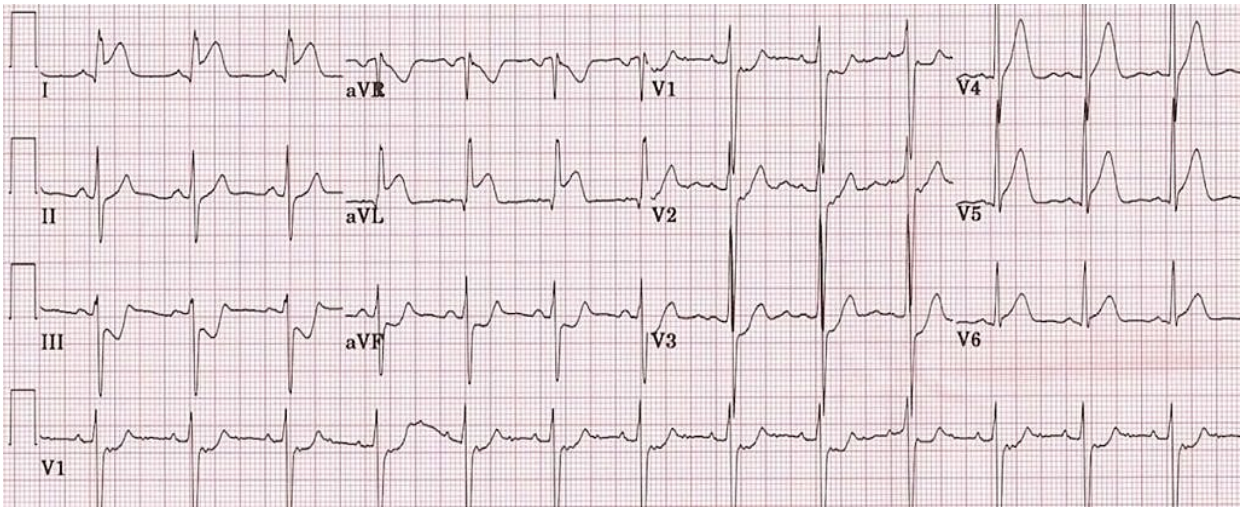


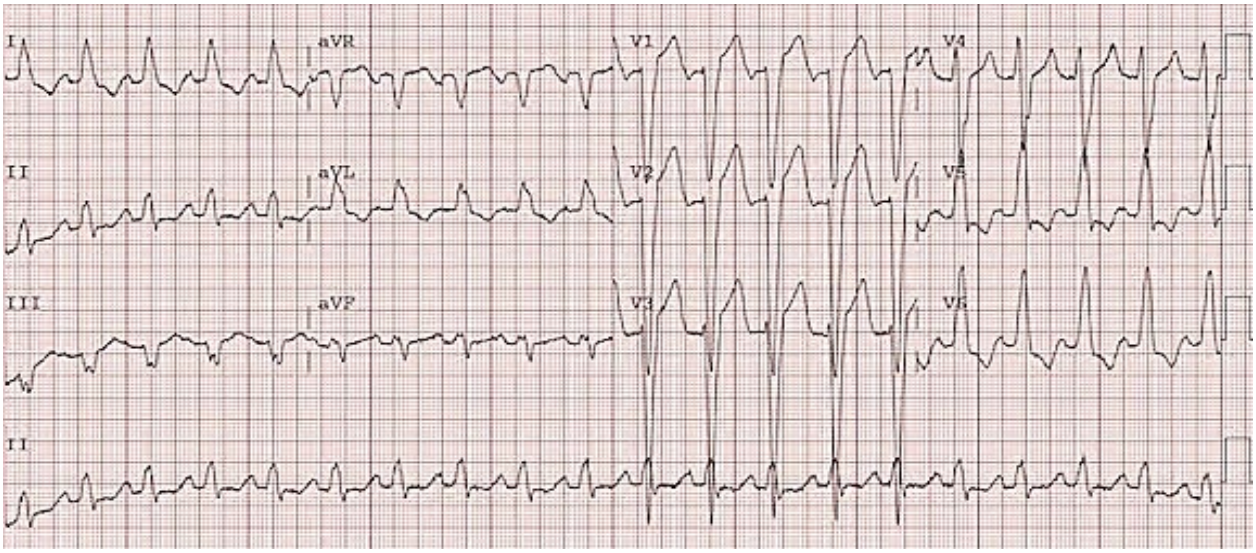
Outside of the standard ECG findings which are diagnostic of a STEMI previously mentioned, there is currently only one universally recognized "STEMI equivalent," which is a left bundle branch block (LBBB) meeting the Sgarbossa's criteria.[19]

There are other highly concerning ECG patterns that include the de Winter pattern, the left main pattern, hyperacute T waves, Wellen's syndrome and posterior MI. These patterns are not considered a STEMI equivalent but emergent/urgent revascularization with PCI that should be considered.[24] ECG interpretation may be complex and urgent teleconsultation with a cardiologist should be considered. ECG changes that should also raise concern for ischemia include ST depressions ≥ 0.5 mm (in ≥ 2 contiguous leads) or T-wave inversion.

1. **LBBB with Sgarbossa's criteria** – Sgarbossa's criteria was developed to identify an acute MI in the setting of a LBBB since this pattern can cause ST- and T-wave changes that make it difficult to identify an MI. The ECG is considered consistent with MI if any of the following three criteria are met and combine to equal ≥ 3 points:[25]
    - ≥ 1 lead with ≥ 1 mm of concordant ST-elevation with the QRS complex (5 points)
    - ≥ 1 lead of V_1-V_3 with ≥ 1 mm of concordant ST-depression with the QRS complex (3 points)
    - ST- elevation of ≥ 5 mm that is discordant with the QRS complex (2 points)
2. **Modified Sgarbossa criteria** (listed below) may outperform the original proposed criteria.[26] Any of the changes listed below are diagnostic of MI in the modified criteria.
    - ≥ 1 lead with ≥ 1 mm of concordant ST elevation with QRS
    - ≥ 1 lead of V1-V3 with ≥ 1 mm of concordant ST depression with QRS
    - ≥ 1 lead anywhere with ≥ 1 mm ST-elevation and proportionally excessive discordant ST-elevation, as defined by ≥ 25% of the depth of the preceding S-wave (an ST:S ratio of ≤ -0.25)

Figure 5. 12-Lead ECG of STEMI using the modified Sgarbossa' s criteria

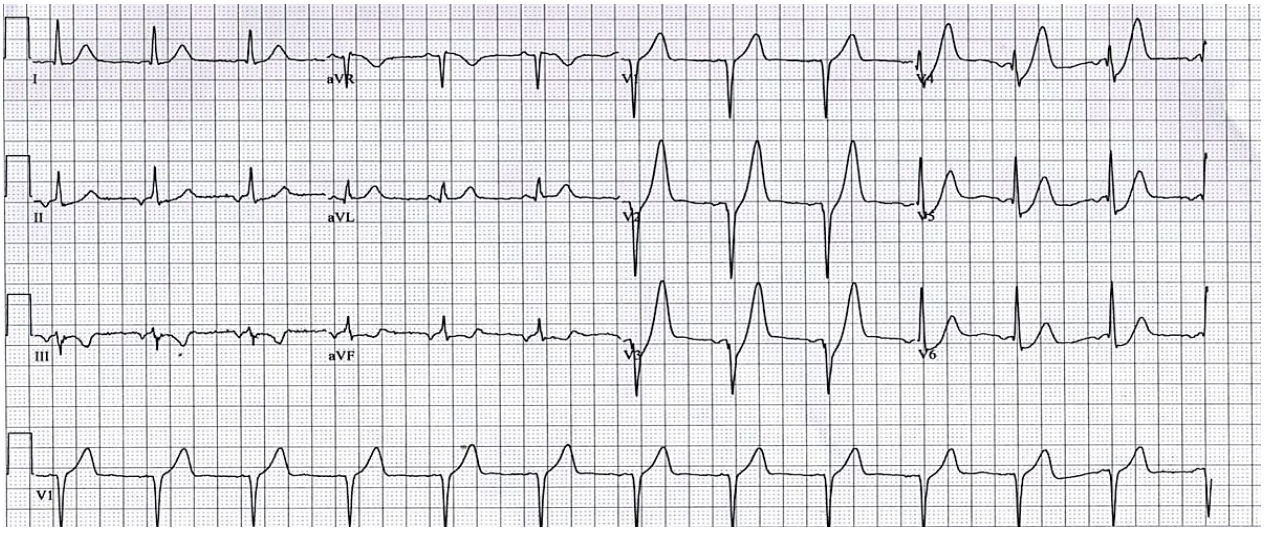
https://epmonthly.com/article/stemi-in-the-presence-of-lbbb/



ECG Patterns Highly Concerning for Myocardial Infarction

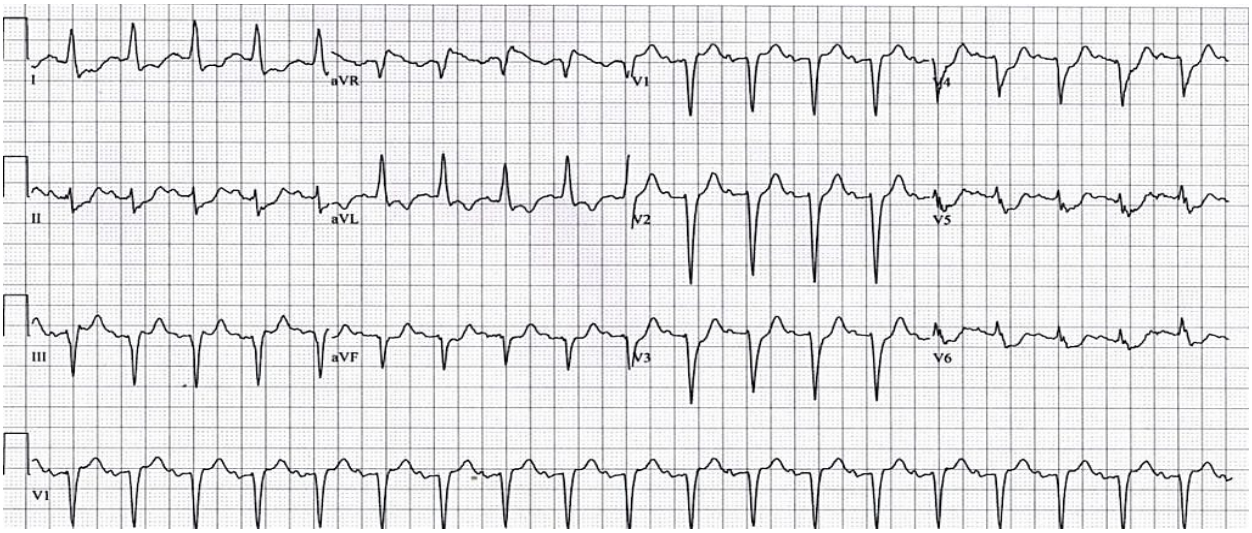
1. **De Winter pattern** – ST-depressions at the J point in V_1-V_6 and tall, peaked, symmetric T-waves are consistent with a de Winter pattern and associated with proximal left anterior descending artery (LAD) occlusion.

Figure 6. 12-Lead ECG of STEMI with De Winter pattern[27]



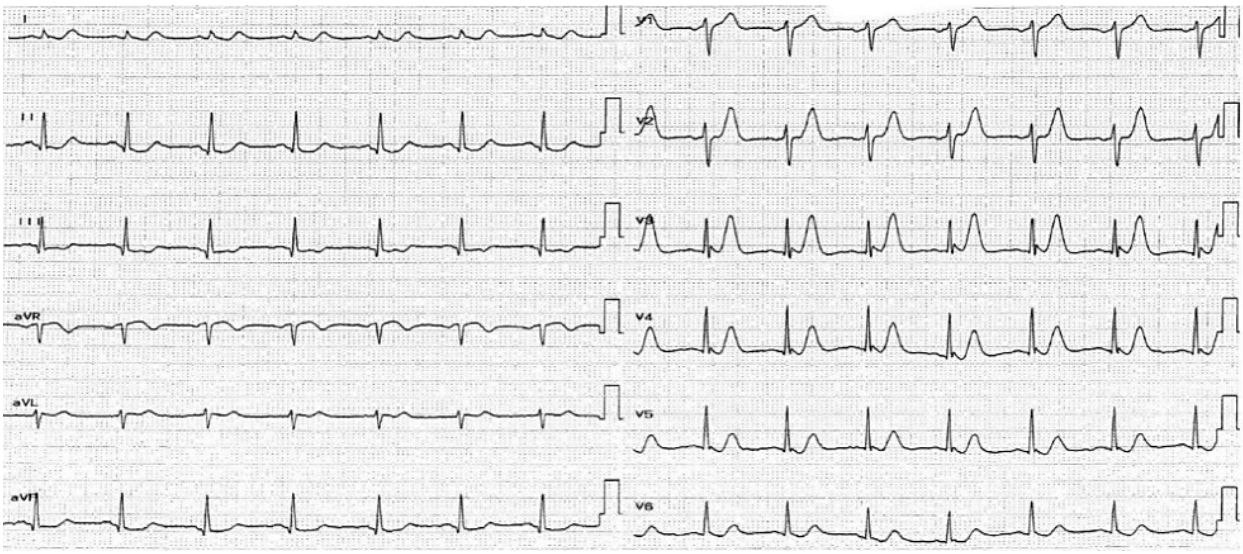
2. **Left main pattern** - Multi-lead ST-depression with coexistent ST-elevation in lead aVR has been described in patients with left main artery or proximal LAD occlusion. This is referred to as a left main pattern.

Figure 7. 12-Lead ECG of STEMI with left main pattern[28]



3. **Hyperacute T waves** – broad, asymmetrically peaked T-waves can be seen in early STEMI.

Figure 8. 12-lead ECG of STEMI with hyperacute T-waves[29]



4. **Wellen's syndrome** – Biphasic T-waves (Type A) or deep, symmetric T-wave inversions (Type B) in leads V_2-V_3 are strongly associated with proximal LAD occlusion. This is referred to as Wellen's syndrome.

Figure 9. 12-Lead ECG of STEMI with biphasic T-waves indicative of Wellen's syndrome[30]

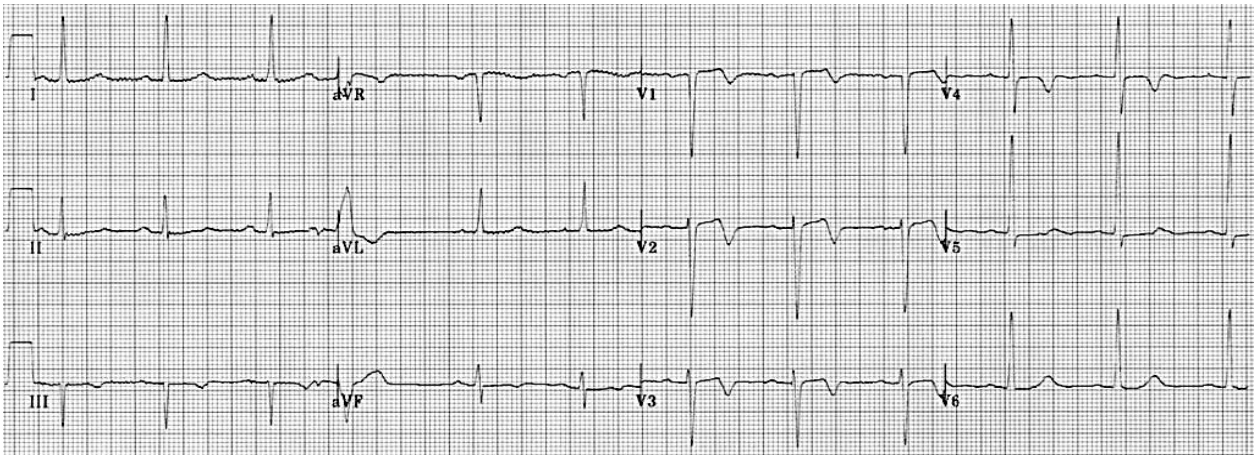


Figure 10. 12-lead ECG of STEMI with deep, symmetrical T-wave inversions indicative of Wellen's syndrome[30]

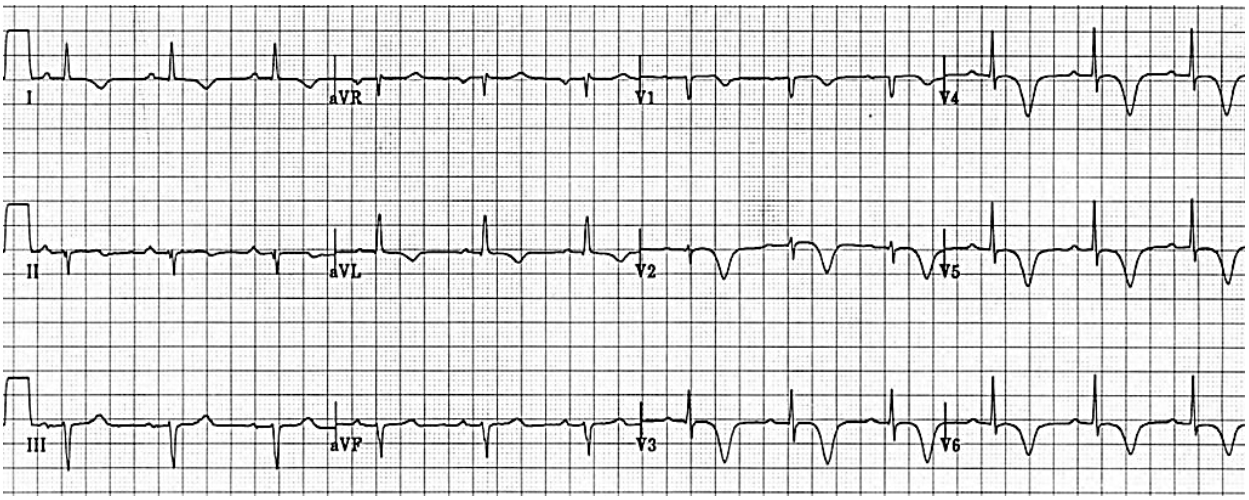

Another indication of acute cardiac ischemia on the ECG is flat or down-sloping ST-depression ≥ 0.5 mm in 2 contiguous leads (Figure 11). If the ST-depressions are seen in leads V_1-V_3 then the next step should be to obtain a 12-lead ECG with posterior leads. This is accomplished by removing leads V_4-V_6 from the patient and placing them at the inferior margin of the left scapula, as shown in Figure 12. If these leads (now called V_7-V_9) show ST-elevation this will be consistent with a posterior STEMI (Figure 13).

Figure 11. 12-lead ECG showing ST-depressions in V_2-V_3 which is suspicious for posterior STEMI[31]

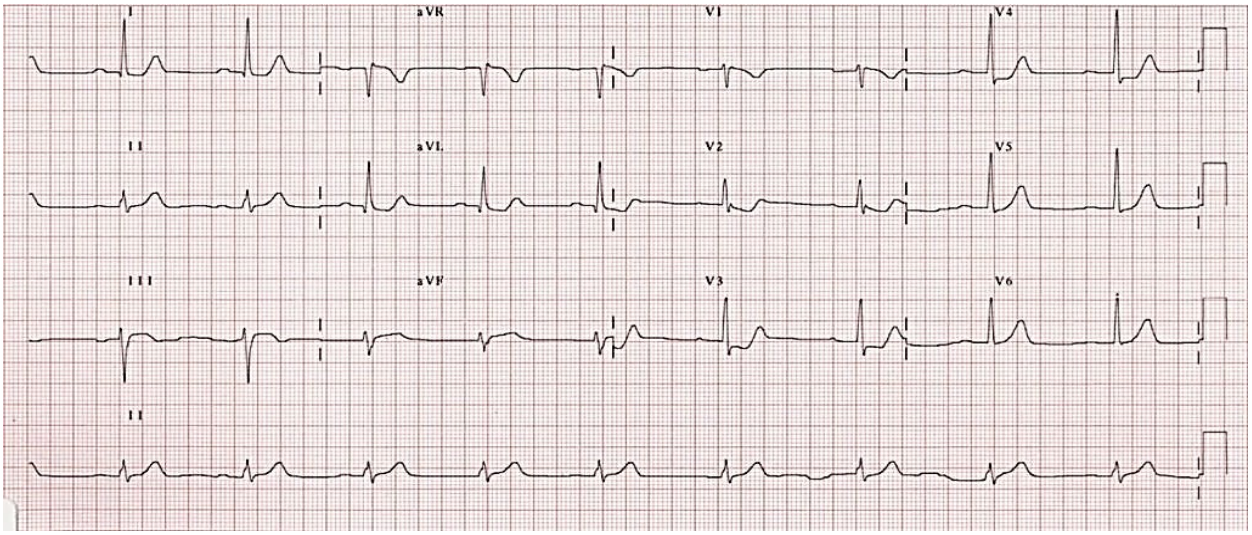

Figure 12. Posterior ECG lead placement[32]

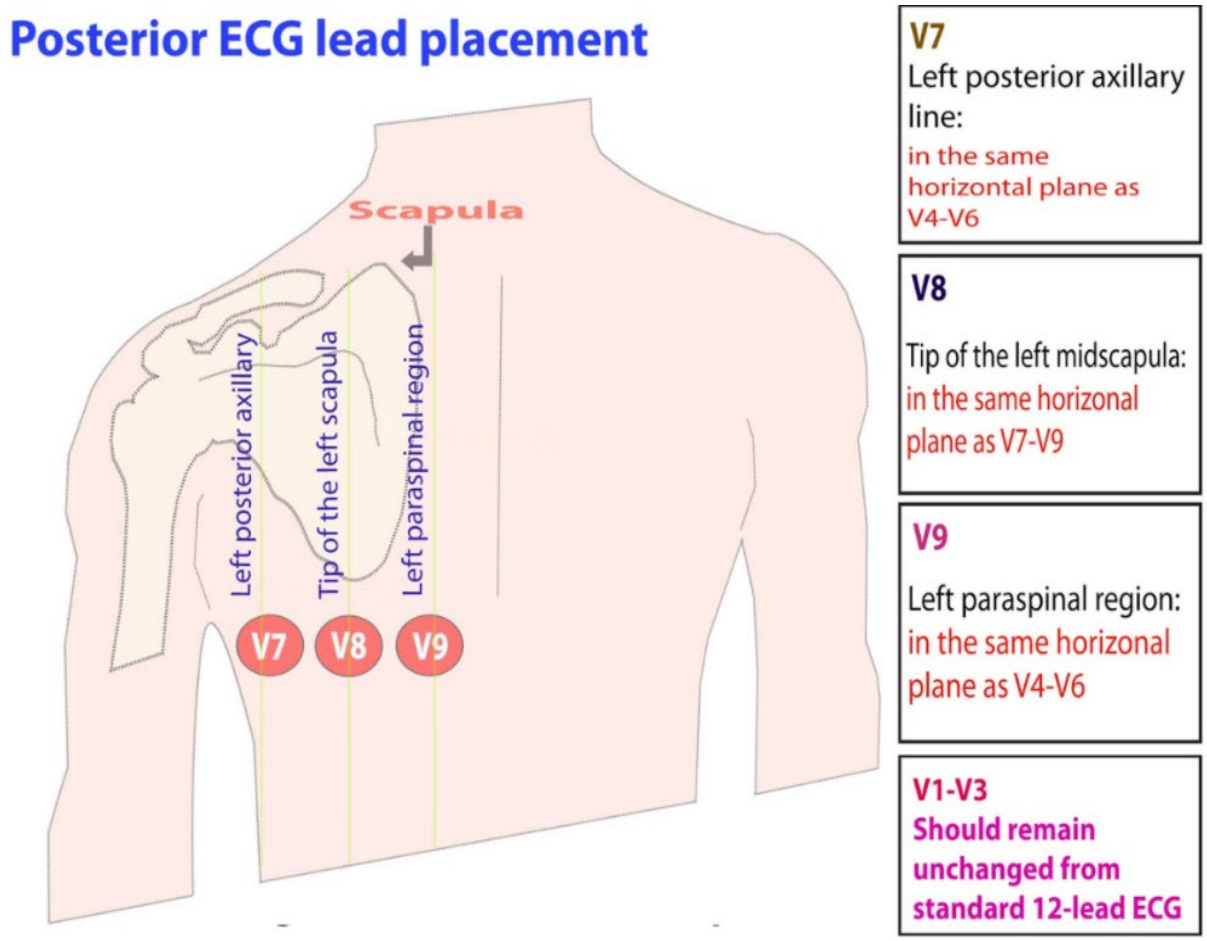

Figure 13. 12-lead ECG STEMI Showing posterior STEMI. Notice ST-elevations in posterior leads V_7-V_9[31]

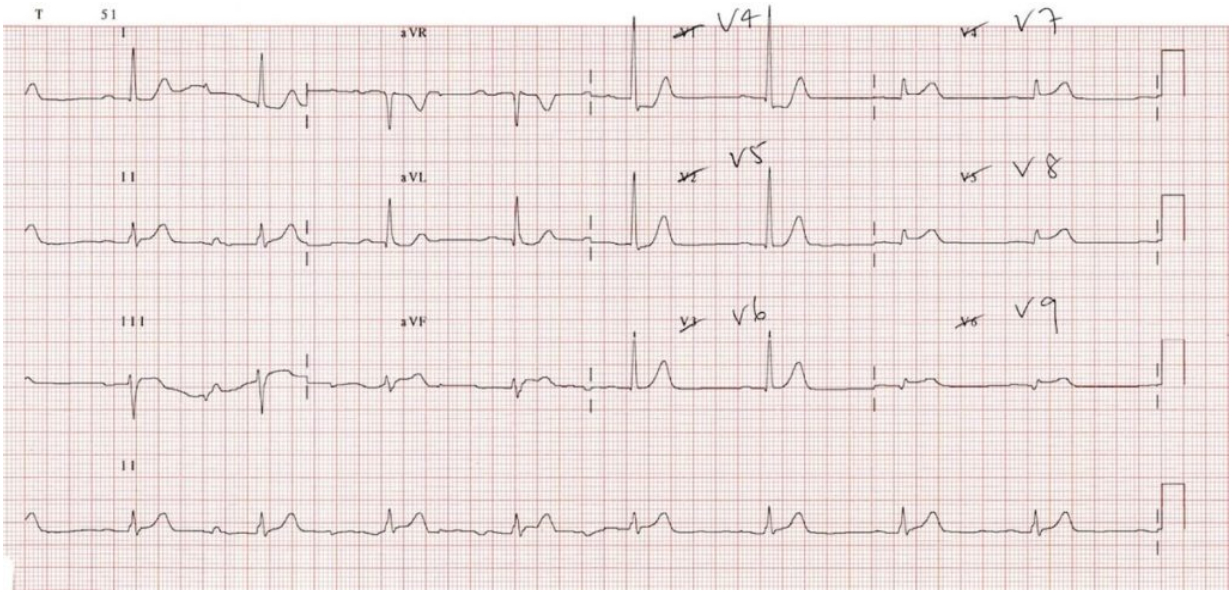
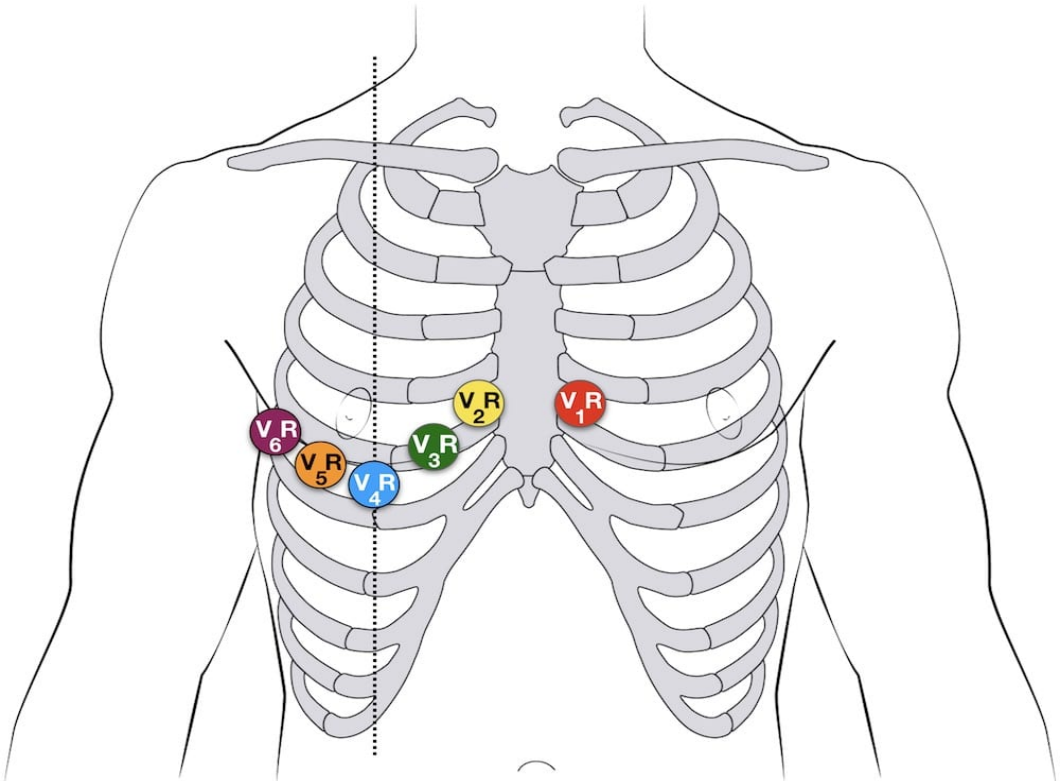


Similarly, if the initial ECG shows evidence of an inferior STEMI (ST-elevation in lead II, lead III, and aVF with reciprocal changes), then consider placing leads V_1-V_6 on the patient as a complete mirror reflection (as shown in Figure 14). If these leads (now called V_1R-V_6R) show ST-elevation this will be consistent with right ventricular infarction.

Figure 14. Right-sided ECG lead placement[33]



If the initial ECG is non-diagnostic (i.e. only one lead meeting ST-elevation criteria but the second contiguous lead ST-elevation is less than 0.1 mV) but the suspicion for ACS is present, then serial ECGs (every 15 minutes for the first hour) should be performed to ensure STEMI is not missed.[17,19]

In contrast to STEMI, UA/NSTEMI can present with a myriad of ECG findings. These may include normal ECGs, nonspecific T-wave inversions, ST-depression or transient ST-elevation.

TREATMENT

MEDICAL THERAPY

Initial medical therapy for ACS includes rapid delivery of antiplatelet agents, anticoagulants and revascularization therapy to include fibrinolytic therapy (if no contraindications exist and PCI is not immediately available). The below sections include lists of common available medications in each class.

Antiplatelet Therapy

Aspirin should be administered immediately to all patients with suspected ACS if no contraindications exist. Once the diagnosis of ACS has been made, a platelet adenosine diphosphate receptor (P2Y).[12] An inhibitor (e.g., clopidogrel, ticagrelor) should then also be administered if no contraindications exist. Initial dosing for all agents is listed below.

1. **Aspirin 162** – 325mg PO x 1 (chewable is preferred, non-enteric coated preferred if chewable not available) then 81mg PO daily.

AND

2. **Clopidogrel (Plavix)**
    a. Age ≤ 75 years old: initial loading dose of 300mg PO x 1 then 75mg PO daily.
    b. Age > 75 years old: initial dose of 75mg PO x 1 then 75mg PO daily.

OR

3. **Ticagrelor (Brilinta)** 180mg PO x1 then 90mg twice daily.
    It is important to note that ticagrelor can cause dyspnea which is thought to be benign, though sometimes concerning to the patient/clinician.

Anticoagulant Therapy

Systemic anticoagulation should be administered as soon as the diagnosis of ACS is made if no contraindications exist. Options for anticoagulants include unfractionated heparin and low molecular weight heparin (LMWH) (i.e. enoxaparin) which exert their anticoagulant properties by indirectly inhibiting thrombin. Another option is factor Xa inhibitor (i.e. fondaparinux). Heparin is administered as a bolus followed by a drip, and its effects are monitored by the activated partial thromboplastin time (aPTT). Currently, typical CCATT that transports patients out of theater do not have the ability to monitor aPTT for heparin drips. Thus, enoxaparin is preferred over a heparin drip when transport is required, given its ease of use. If enoxaparin or another LMWH is not available, then consideration of fondaparinux should be utilized if available. If heparin is the only agent available, then it should be given. Dosing consideration for transport would be decided based on an aPTT immediately prior to the

flight. For patients that have a known or suspected history of heparin induced thrombocytopenia, fondaparinux should be used. Anticoagulation should continue for at least 48 hours or until revascularization.

The following are the dosing for each agent listed below:

1. **Enoxaparin (Lovenox) – *preferred agent***
    a. **STEMI dosing:**
        - Age < 75 years: single 30mg IV bolus **plus** 1mg/kg SubQ (maximum 100mg for the first 2 doses only). then 1mg/kg SubQ every 12 hours
        - Age ≥ 75 years: 0.75 mg/kg SubQ every 12 hours
    b. **NSTEMI dosing**: 1mg/kg SubQ every 12 hours.
    c. Consult pharmacy to adjust this dose if there is any renal injury (rise in creatinine).

OR

2. **Heparin Sulfate**
    a. **STEMI dosing**: 60 U/kg initial bolus IV (4,000 U maximum), then 12 U/kg/hr (maximum 1,000 u/hr) infusion.
    Maintain aPTT 1.5–2.0 times control (50-70s).
    b. **NSTEMI dosing**: 60 U/kg initial bolus IV (5,000 U maximum), then 12 U/kg/hr (maximum 1,000 U/hr) infusion.
    Maintain aPTT 1.5–2.0 times control (50-70s).

OR

3. **Fondaparinux (Arixtra)**
    a. **STEMI dosing**: 2.5 mg IV x1 then 2.5 mg SubQ daily.
    b. **NSTEMI dosing**: 2.5 mg SubQ daily.

REPERFUSION THERAPY

Prompt reperfusion is the mainstay of STEMI care. Whenever possible, a patient presenting with STEMI should be transferred emergently to the nearest medical facility that can perform urgent PCI as it is considered the optimal treatment. This should be achieved within 2 hours of patient arrival.[13] In the event that door-to-balloon time cannot be achieved within 2 hours, fibrinolytics should be given instead. In the deployed setting, PCI, may be prohibitively far away, and thus rapid delivery of fibrinolytic therapy is the method of choice for revascularization. Fibrinolytic therapy should be administered within 30 minutes of STEMI diagnosis. There are absolute and relative contraindications to administration of fibrinolytics (listed in Appendix A). This list should be meticulously reviewed step by step prior to administration of these agents. The two most common agents available are listed below with their dosing. Fibrinolytics should be offered to patients with symptom duration of 12 hours or less. It is recommended that expert consultation with the theater cardiology consultant be used prior to administering fibrinolytics in the 12 to 24 hour period.

***Note**: Dual antiplatelet therapy, systemic anticoagulation, beta blocker and high dose statins should still be given even when fibrinolytics are given.*

1. **Tenecteplase (TNKase) – *preferred agent***
   a. < 60 kg: 30mg IV bolus x 1
   b. 60-69 kg: 35mg IV bolus x 1
   c. 70-79 kg: 40mg IV bolus x 1
   d. 80-89 kg: 45mg IV bolus x 1
   e. ≥ 90 kg: 50mg IV bolus x 1

OR

2. **Alteplase (Activase)**
   a. ≤ 67 kg: 15mg IV bolus over 1-2 minutes, then infusion of 0.75 mg/kg (maximum 50mg) over 30 minutes, then infusion of 0.5 mg/kg (maximum 35mg) over 60 minutes.
   b. 67 KG: 15mg IV bolus over 1-2 minutes, then infusion of 50mg over 30 minutes, then infusion of 35mg over 60 minutes (maximum total dose 100mg).

NOTE: In contrast to STEMI, fibrinolytics are contraindicated in UA/NSTEMI patients.

STATIN THERAPY

Regardless of the patient's blood lipid levels, high dose Statin therapy should also be administered during the initial presentation (within the first 2 hours) of ACS. The following are the two therapy options to administer:

1. **Atorvastatin (Lipitor)** 80mg PO x 1 then 80mg nightly.

OR

2. **Rosuvastatin (Crestor)** 20-40mg PO x1 then 20-40mg PO daily.

SUPPORTIVE THERAPY

Supplemental Oxygen

Administer ring oxygen in patients with ACS is recommended only when oxygen saturation levels are < 90%, to avoid potential harm from oxygen free radicals and further hyperoxia coronary vasoconstriction.

Analgesia

Decreasing the pain response can block sympathetic activity and relieve anxiety, which decreases myocardial oxygen consumption. The routine use of morphine for pain control is not recommended since this has been shown to increase the risk of mortality in ACS.[34] Nitroglycerin a vasodilator, opens blood vessels to improve blood flow; treating angina symptoms, such as chest pain or pressure that

happens when there is not enough blood flowing to the heart. Nitroglycerin dilates coronary arteries and relaxes vascular smooth muscles, resulting in decreased preload/afterload and decreased myocardial oxygen demand.

Nitroglycerin

1. Initial dose of 0.3 – 0.4 mg sublingually every 5 minutes for 3 doses; afterwards an intravenous infusion may be considered.
2. If a nitroglycerin IV infusion is administered, start at 5-10 mcg/ minute (min) and titrate as needed to relieve anginal symptoms in increments of 5 mcg/min every 5-10 minutes up to 20 mcg/min; if angina persists at a dose of 20 mcg/min then increase the dosage by 10-20 mcg/min every 3-5 minutes to a maximum dose of 400 mcg/min.
3. Nitroglycerin is contraindicated in patients who have a systolic blood pressure < 100 mmHg, who have used phosphodiesterase inhibitors in the last 24 hours, or who have evidence of inferior STEMI on ECG.

Beta Blockers

Beta blockers block sympathetic stimulation and decrease the heart rate. They have been shown to decrease early development of lethal ventricular dysrhythmias as well as improve long term left ventricular remodeling. Although the American Heart Association and American College of Cardiology recommend that beta blockers be initiated in the first 24 hours of NSTEMI, there have been studies that show early administration of beta blockers in the ED was associated with higher rates of shock or death than later administration.[35] Initiate this medication after the patient has been hospitalized in either the Role 2 or Role 3. Beta blockers should be withheld in patients with systolic blood pressure < 100 mmHg, heart rate < 60 beats per minute, evidence of pulmonary edema, second or third degree heart block, severe reactive airway disease, or elevated risk of cardiogenic shock.

1. **Metoprolol tartrate** (immediate release) – 12.5 mg PO every 6 – 12 hours.

OR

2. **Metoprolol succinate** (extended release) – 25-50 mg PO once daily.

OR

3. **Atenolo**l – 50-100 mg PO every 12 to 24 hours.

ACE Inhibitors and ARBs

Angiotension converting enzyme (ACE) inhibitors that are initiated within 24 hours to 16 days after an acute MI show improved patient survival as well as improved left ventricular ejection fraction. ACE inhibitors are contraindicated in systolic blood pressure < 100 mmHg, history of bilateral renal artery stenosis, hyperkalemia, or prior worsening renal function with ACE inhibitors. It is reasonable to administer angiotensin receptor blockers (ARBs) in patients who cannot tolerate ACE inhibitors.

1. **Captopril** - initial dose of 6.25 mg PO, which is increased at 6 to 8 hour intervals to a maximum of 50 mg PO three times daily as long as the systolic blood pressure is above 90 to 100 mmHg.

OR

2. **Enalapril** - initial dose 2.5 mg PO daily increased up to 20 mg PO twice daily.

OR

3. **Lisinopril** - initial dose 2.5 mg PO daily increased to a maximum of 10 mg PO daily.

OR

4. **Losartan** - 25 to 50 mg PO once daily depending on initial blood pressure.

Other Therapies

If indicated continue to utilize Proton pump inhibitors. Nonsteroidal anti-inflammatory drugs (NSAIDs) on the other hand should be avoided in these patients due to their increased risk of adverse cardiovascular events and the increased risk of bleeding when combined with the other mainstay treatments of ACS such as antiplatelet and anticoagulant therapy. Routine use of blood transfusion in the setting of ACS is associated with increased mortality.[13,36,37] It is recommended to avoid transfusion unless the hemoglobin level is < 8 g/DL .

COMPLICATIONS TO THERAPY

BLEEDING COMPLICATIONS

Bleeding complications are likely to be rare but they may be encountered and should be closely watched. Neurological checks should occur every 15 minutes for the first hour and then 30 minutes for the next 6 hours to monitor for intracranial bleeding. Normotension should be strived for while SBP > 160 mmHg should be avoided. Once life-threatening bleeding is identified, stop all antiplatelet agents, anticoagulants, and fibrinolytics. Specific reversal therapies unique to life-threatening bleeding due to thrombolysis are listed below.[38] In the case of suspected intracranial bleeding, obtain an emergent CT head and consult neurosurgery if an intracranial bleed is actually present.

1. Administer Cryoprecipitate - 10 units IV.
2. Administer tranexamic acid (TXA) – 10-15 mg/kg IV.
3. Stop all antiplatelet, anticoagulant, and fibrinolytics.

COMPLICATIONS ASSOCIATED WITH MI

There are both early and late complications associated with MI. Early complications will be the focus here as these are the ones likely to be seen in the deployed setting during the initial hours to days of treatment.

CARDIOGENIC SHOCK

Cardiogenic shock is best defined as SBP < 90 mmHg for 30 minutes or SBP > 90 mmHg on vasopressors with evidence of end organ damage from a cardiovascular origin. The patient may have evidence of pulmonary edema (worsening dyspnea, crackles, worsening chest x-ray) or evidence of peripheral hypoperfusion (weak pulses, cold extremities). Listed below are the vasopressor/inotropic agents that should be utilized in this situation.[39]

1. **Norepinephrine** (preferred first line agent) - 5 – 20 mcg/min IV. Start at 5 mcg/min and increase by 2-5 mcg/min q15 minutes.
2. **Dopamine** - 0.5 to 20 mcg/kg/minute IV (lower doses preferred).

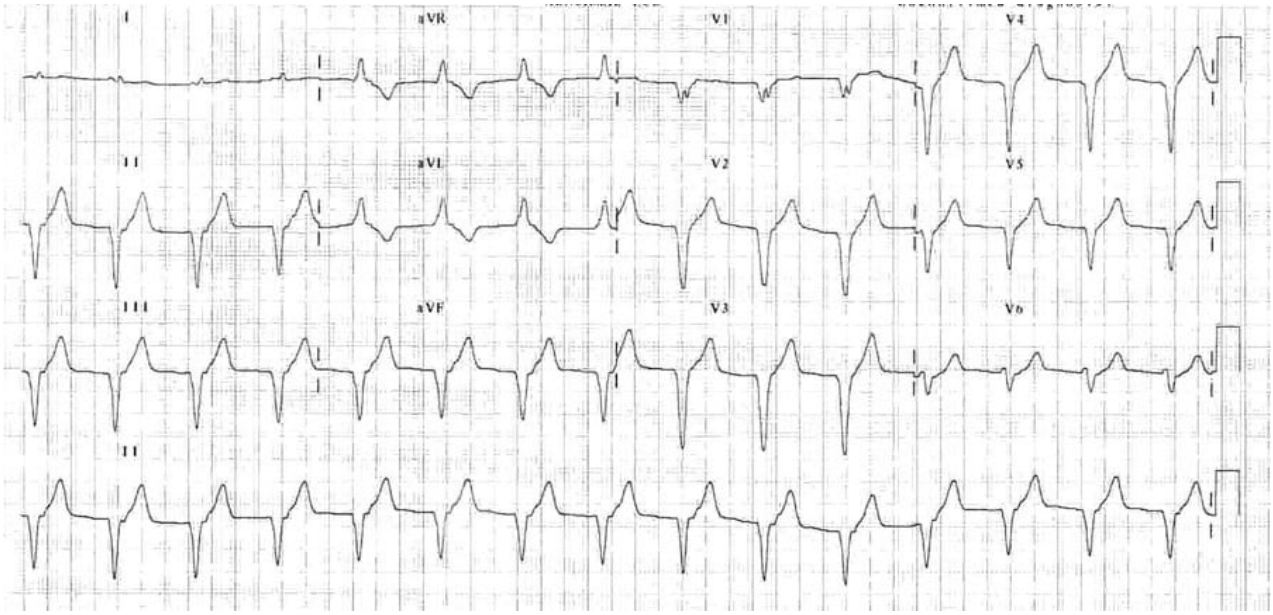
MECHANICAL COMPLICATIONS

Mechanical complications primarily manifest as either acute chordal rupture of the mitral valve, ventricular septal rupture, or left ventricular free wall rupture. These typically occur within the first 24 hours but can present within a week as well. The use of fibrinolytics is also a risk factor for an acute ventricular septal rupture and left ventricular free wall rupture. Medical therapy is only temporary with a high mortality rate for those unable to undergo surgical correction. Echocardiography is the modality of choice for rapid diagnosis. This can show pericardial effusion when associated with left ventricular free wall rupture.

ARRHYTHMIAS

There are multiple different tachy- and brady-dysrhythmias that can occur with acute MI. Most can be addressed using ACLS protocols. The most common rhythm following reperfusion is accelerated idioventricular rhythm (Figure 14). This manifests as a wide complex QRS rhythm (as you would see with ventricular tachycardia) with heart rates in the 50 – 110 bpm; it is benign and requires no intervention.[40] Patients are typically asymptomatic with normal vital signs otherwise, and it should resolve spontaneously.

Figure 15. 12-lead ECG STEMI Accelerated idioventricular rhythm after STEMI reperfusion[40]



CONSIDERATIONS DURING MECHANICAL VENTILATION

MEDICATIONS

If the patient with ACS begins to develop shock and is unable to protect his/her airway, then you might have to perform endotracheal intubation (Refer to Airway Management CPG). The following considerations should be made regarding induction and post-intubation sedation medications:[41]

1. **Ketamine** should be avoided in patients with acute MI or heart failure due to increased myocardial oxygen consumption and negative inotropic effects.
2. **Etomidate** is recommended for induction of anesthesia given its neutral effects on hemodynamics.
3. **Propofol** should be used with caution in induction, given its ability to cause acute hypotension. It is generally safe for maintenance of anesthesia, however, caution should be used in patients with severe cardiac disease as propofol has also been shown to exacerbate cardiac dysfunction through its negative inotropic effects.
4. **Versed/Fentanyl** is acceptable for induction/maintenance of anesthesia.

VENTILATOR SETTINGS

High intrathoracic pressures affect the right and left ventricles differently. High intrathoracic pressures impair right ventricular filling, yet reduces left ventricular afterload. In a patient's post-MI that require mechanical ventilation, minimization of intrathoracic pressures for a patient with inferior/right ventricular infarction is essential to maintain cardiac output. PEEP and tidal volume should be minimized as much as possible.

CONSIDERATIONS DURING EVACUATION

The care of ACS patients at deployed locations is limited by the fact that cardiac care is provided in austere locations without rapid access to higher levels of care. While medical therapies can stabilize patients for short periods of time, any complications that arise do not have the benefit of being treated urgent/emergently in a cardiac catheterization laboratory. A plan for urgent MEDEVAC/aeromedical evacuation to a PCI capable center should be initiated as soon as they are diagnosed with ACS and initiated medical therapy.

TELEMEDICINE/CARDIOLOGY CONSULTANT

The first cardiology consultant within the evacuation chain should be consulted immediately for patients diagnosed with a STEMI or UA/NSTEMI at deployed locations. Diagnosis and treatment of ACS should be guided by expert consultation, to include electronic transmission of ECGs (by whatever means available).

MEDEVAC

When possible, all patients diagnosed with or with high suspicion of ACS at Role 1 or 2 facilities should be moved to a Role 3 facility (preferably a facility with a cardiologist) as soon as possible.

HOST NATION

At times host nations (HNs) have facilities that meet U.S. standards for medical care. If relationships with these facilities have been established and have been utilized for emergent care of U.S. personnel, then their use should be considered for emergent PCI in the following situations:

1. **STEMI** – PCI at a HN facility is preferred over fibrinolysis since this is the primary treatment for STEMI. If the facility or total transport time exceeds 120 minutes, then administer fibrinolysis (with cardiology teleconsultation) and continue coordinating transport to the HN PCI lab.
2. **UA/NSTEMI** – refractory angina, ischemic ECG changes, hemodynamic instability (with or without cardiogenic shock) or refractory arrhythmias after receiving medical therapy.

AEROMEDICAL EVACUATION

Aeromedical evacuation of all ACS patients should adhere to the following principles when possible due to the evolving nature of the disease and limited ability to fully handle the complications that come with this disease process.

1. All aeromedical evacuation of ACS patients should be evacuated by CCATT or equivalent level of care.
2. Missions should be requested as URGENT unless otherwise designated with cardiology consultation.
3. All in flight treatment should follow the recommendations put forth in the previous sections of the CPG.

IN-FLIGHT CONSIDERATIONS

1. Maintain O_2 saturations > 90%.
2. Red blood cell transfusion should be avoided unless the hemoglobin level is < 8 g/dl in patients without active ischemia.[13,36]
3. In the event of an inflight STEMI (new vs. reinfarction), then thrombolytics should be given unless a contraindication exists (see Appendix A).
4. If the patient becomes unstable in-flight, consideration of diversion to the closest location with PCI capabilities should be strongly considered. An unstable patient is one who has ongoing ischemia and the presence of either:
    a. Hypotension/shock primarily due to suspected cardiovascular causes.
    b. Recurrent ventricular arrhythmias that are unable to be controlled with ACLS medications (e.g., beta blockers, amiodarone).

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

1. All patients presenting with a STEMI receive dual antiplatelet therapy, systemic anticoagulation and fibrinolytic therapy (unless contraindicated) within 30 minutes of arrival to a facility with these therapies available.
2. In facilities without fibrinolytics, dual antiplatelet therapy and systemic anticoagulation is administered before transfer to a higher level of care.

INTENT (EXPECTED OUTCOMES)

1. All patients with concern for STEMI or NSTEMI will have a documented consultation/teleconsultation with a cardiologist.
2. All patients diagnosed with STEMI are transferred to a PCI center.

PERFORMANCE/ADHERENCE MEASURES

1. Dual antiplatelet therapy and systemic anticoagulation are given within 30 minutes of arrival at a facility with these therapies available.
2. Fibrinolytic therapy is given within 30 minutes of confirmation of a STEMI in facilities that have these therapies, or door to PCI center within 120 minutes with facilities that can arrange for a transfer to a PCI center.
3. Consultation/teleconsultation with a cardiologist is documented for all patients with concern for STEMI or NSTEMI.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry
- Theater Medical Data Store

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting frequency will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief, Program Manager and PI Branch.

RESPONSIBILITIES

It is the Chief of Trauma or equivalent's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: FIBRINOLYTICS ABSOLUTE AND RELATIVE CONTRAINDICATIONS IN STEMI

The following table provides the absolute and relative contraindications health factors in regards to administering fibrinolytics in STEMI.

Table A-1. Absolute and Relative Contraindications

Absolute	Relative
Any prior intracranial hemorrhage	History of chronic, severe, poorly controlled hypertension
Known structural cerebral vascular lesion (e.g., arteriovenous malformation)	Significant hypertension on presentation (SBP >180 mm Hg or DBP >110 mm Hg)
Known malignant intracranial neoplasm (primary or metastatic)	History of prior ischemic stroke >3 months
Ischemic stroke within 3 months (EXCEPT acute ischemic stroke within 4.5 hours)	Dementia
Suspected aortic dissection	Known intracranial pathology not covered in absolute contraindications
Active bleeding or bleeding diathesis (excluding menses)	Traumatic or prolonged (>10 minutes) CPR
Significant closed-head or facial trauma within 3 months	Major surgery (< 3 weeks)
Intracranial or intraspinal surgery within 2 months	Recent (within 2 to 4 weeks) internal bleeding
Severe uncontrolled hypertension (unresponsive to emergency therapy)	Noncompressible vascular punctures
For streptokinase, prior treatment within the previous 6 months	Pregnancy
	Active peptic ulcer
	Oral anticoagulant therapy

The American College of Cardiology Foundation/American Heart Association guideline for the management of ST-elevation myocardial infarction: executive summary. Circulation. 2013;127:529–555 https://www.ahajournals.org/doi/10.1161/CIR.0b013e3182742c84 Accessed May 2021.

APPENDIX B: MAJOR ADVERSE CARDIAC EVENT (MACE) HEART SCORE

This section provides the predictive HEART score for a 6-week risk of MACE.

MACEs are defined as the following:

- Acute myocardial infarction (MI)
- Percutaneous coronary intervention (PCI)
- Coronary artery bypass graft (CABG)
- Coronary angiography revealing procedurally correctable stenosis managed conservatively
- Death due to any cause

Table B-1. MACE Heart Score

History	Highly suspicious	2
	Moderately suspicious	1
	Slightly or non-suspicious	0
ECG	Significant ST-depression	2
	Nonspecific repolarization disturbance	1
	Normal	0
Age	≥ 65 years	2
	> 45 - < 65 years	1
	≤ 45 years	0
Risk Factors*	≥ 3 risk factors, *or* history of atherosclerotic disturbance	2
	1 to 2 risk factors	1
	No risk factors known	0
Troponin	≥ 3x normal limit	2
	> 1 - < 3x normal limit	1
	≤ normal limit	0

The following are MACE risk factors:

- Hypertension
- Hypercholesterolemia
- Diabetes mellitus
- Obesity (body max index > 30 kg/m2)
- Smoking (current, or smoking cessation < 1 month)

- Positive family history for coronary artery disease
- Atherosclerotic disease
- Prior MI, PCI, CABG, cerebrovascular accident/transient ischaemic attack or peripheral artery disease

The following are the score levels for MACE:

- 0 – 3: low risk; 1.7% found to have MACE
- 4 – 6: moderate risk; 16.6% found to have MACE
- 7 – 10: high risk; 50.1% found to have MACE

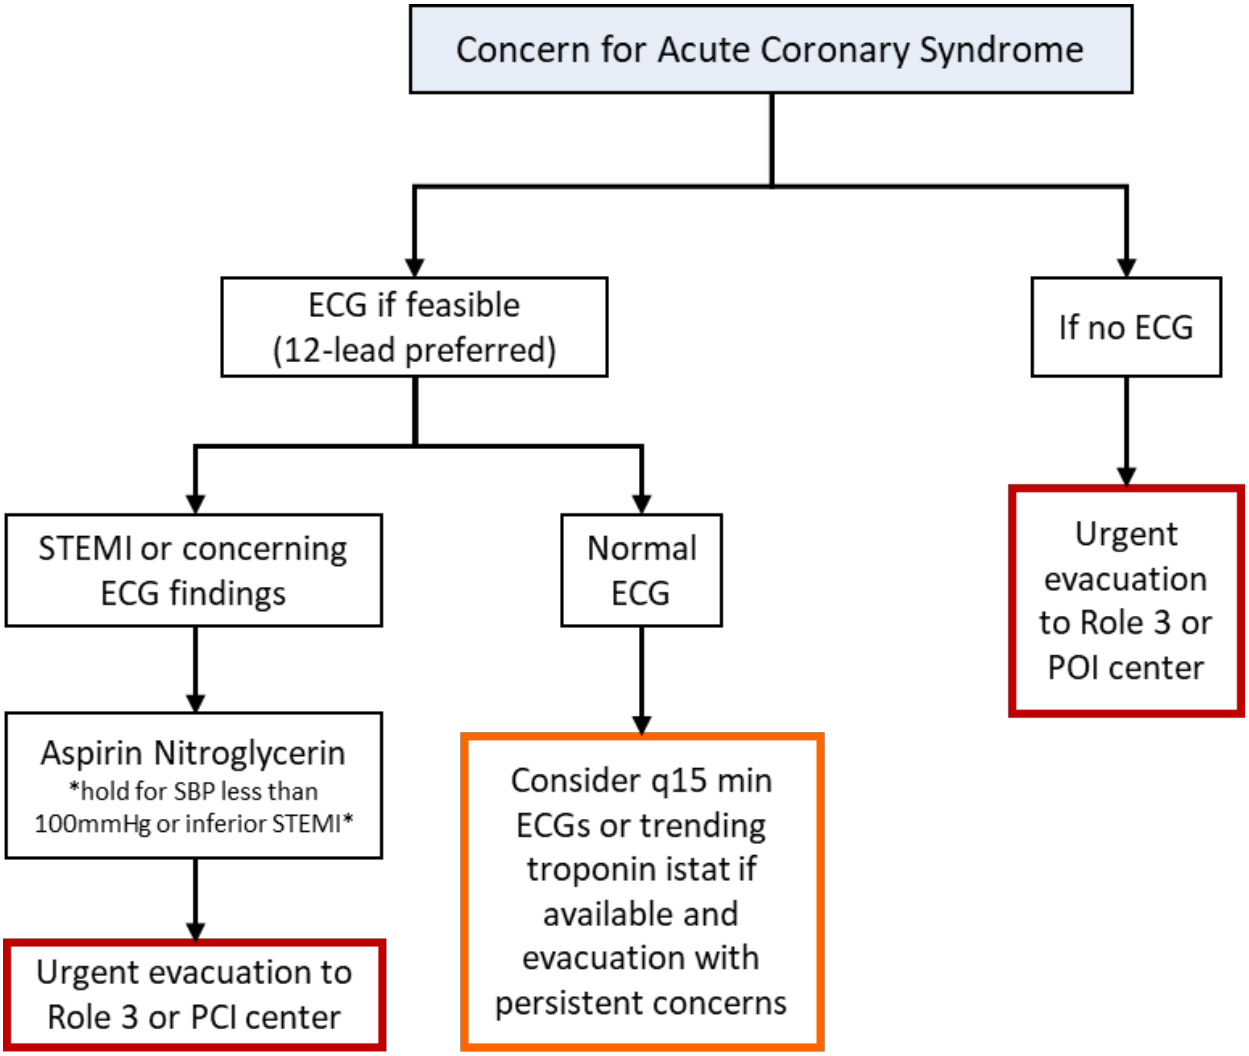
APPENDIX C: ACS ROLES

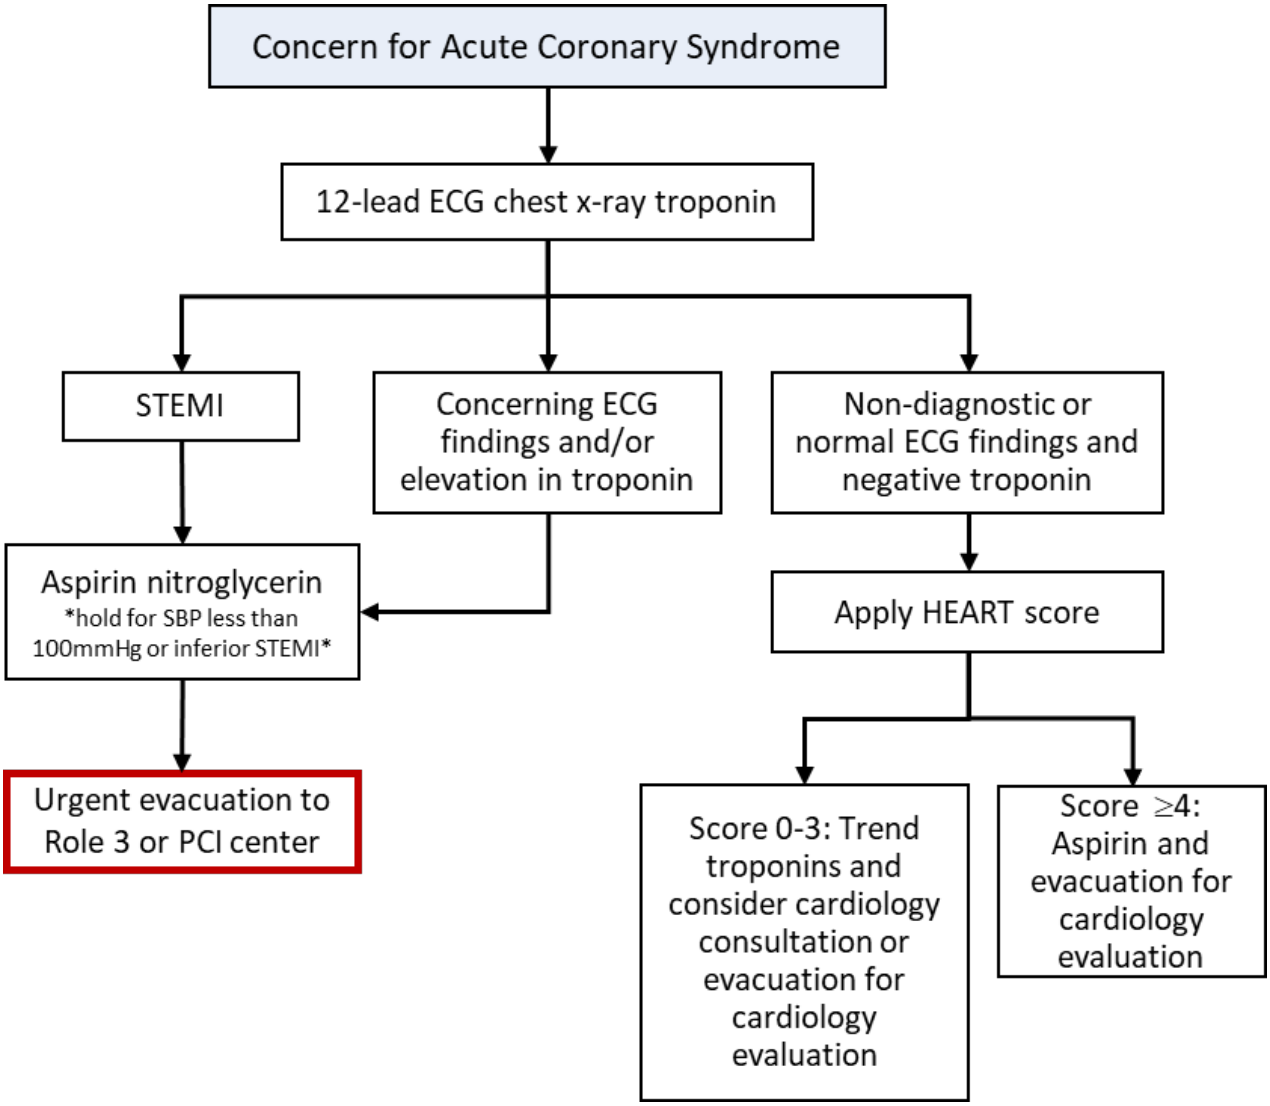
The following figures provide the ACS roles for care.

Figure C-1. ACS Role 1



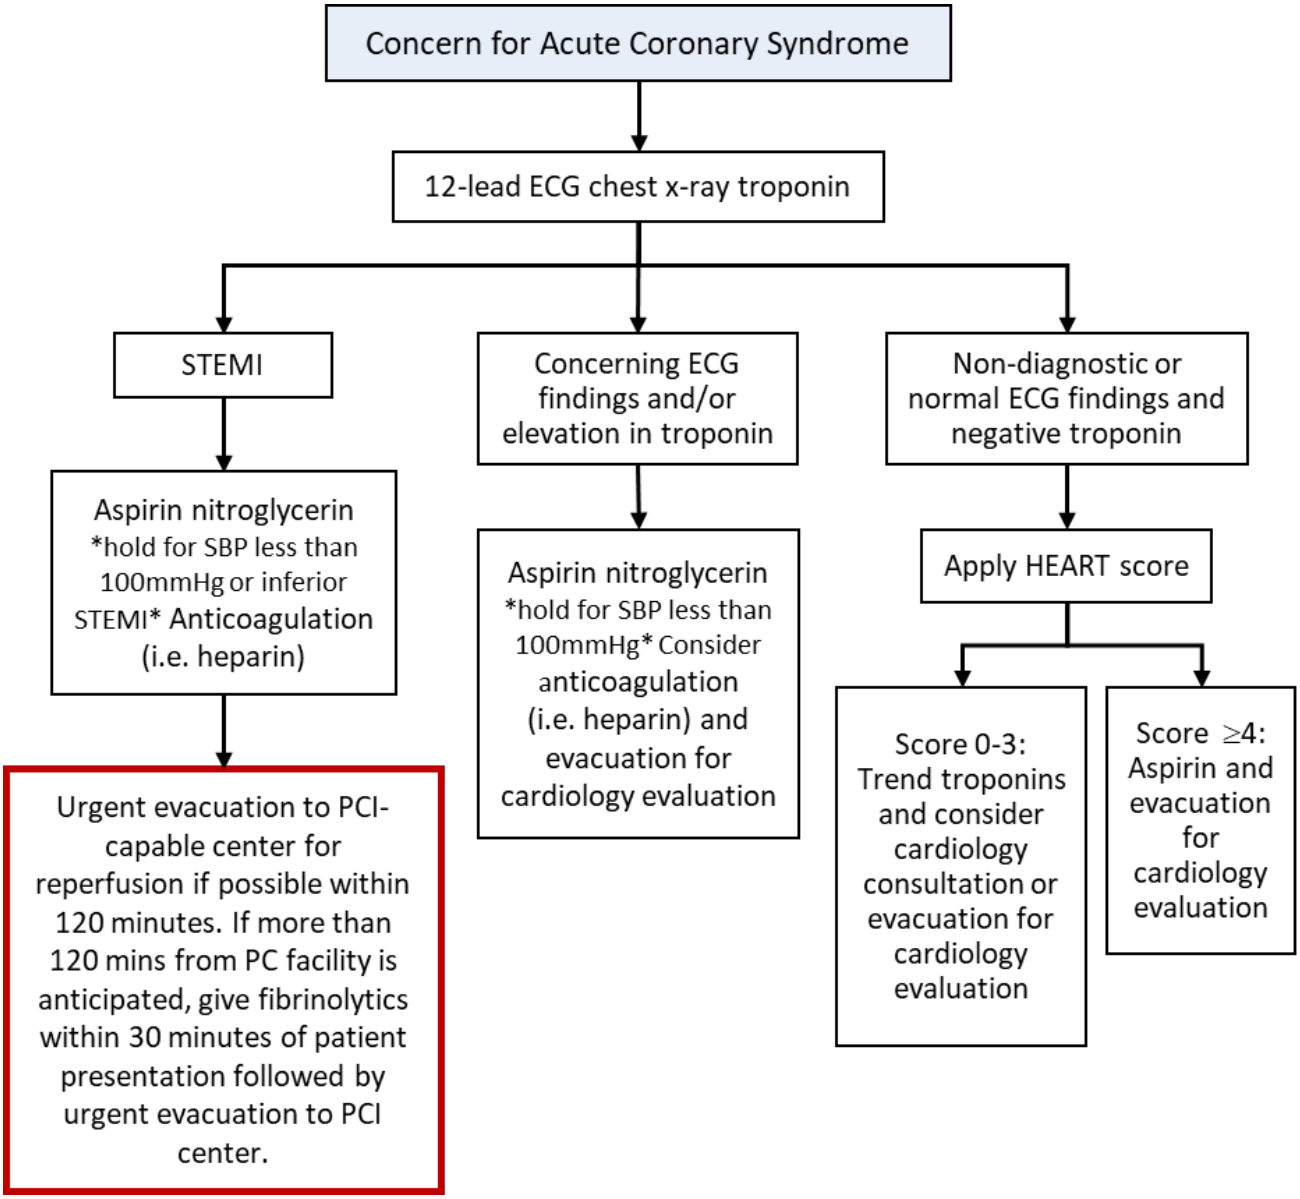
Concern for Acute Coronary Syndrome
ECG if feasible (12-lead preferred)
If no ECG
STEMI or concerning ECG findings
Normal ECG
Urgent evacuation to Role 3 or POI center
Aspirin Nitroglycerin
hold for SBP less than 100mmHg or inferior STEMI
Consider q15 min ECGs or trending troponin istat if available and evacuation with persistent concerns
Urgent evacuation to Role 3 or PCI center

Figure C-2. ACS Role 2



Concern for Acute Coronary Syndrome
12-lead ECG chest x-ray troponin
STEMI
Concerning ECG findings and/or elevation in troponin
Non-diagnostic or normal ECG findings and negative troponin
Aspirin nitroglycerin
hold for SBP less than 100mmHg or inferior STEMI
Apply HEART score
Urgent evacuation to Role 3 or PCI center
Score 0-3: Trend troponins and consider cardiology consultation or evacuation for cardiology evaluation
Score ≥4: Aspirin and evacuation for cardiology evaluation

Figure C-3. ACS Role 3



Concern for Acute Coronary Syndrome
12-lead ECG chest x-ray troponin
STEMI
Concerning ECG findings and/or elevation in troponin
Non-diagnostic or normal ECG findings and negative troponin
Aspirin nitroglycerin *hold for SBP less than 100mmHg or inferior STEMI* Anticoagulation (i.e. heparin)
Aspirin nitroglycerin *hold for SBP less than 100mmHg* Consider anticoagulation (i.e. heparin) and evacuation for cardiology evaluation
Apply HEART score
Urgent evacuation to PCI-capable center for reperfusion if possible within 120 minutes. If more than 120 mins from PC facility is anticipated, give fibrinolytics within 30 minutes of patient presentation followed by urgent evacuation to PCI center.
Score 0-3: Trend troponins and consider cardiology consultation or evacuation for cardiology evaluation
Score ≥4: Aspirin and evacuation for cardiology evaluation

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Acute Extremity Compartment Syndrome (CS) and the Role of Fasciotomy in Extremity War Wounds (CPG ID: 17)

Guide providers in the evaluation and treatment of patients with extremity war wounds, including the role of prophylactic and therapeutic fasciotomy.

GOAL

This CPG provides an overview of acute extremity Compartment Syndrome (CS) and present a standardized approach to guide providers in the evaluation and treatment of patients with extremity war wounds, including the role of prophylactic and therapeutic fasciotomy.

BACKGROUND

CS is a common, controversial, and disabling problem in extremity war injuries. Seven to 11% of civilian tibia fractures result in compartment syndrome.[1-5] A similar incidence can be expected in cases of fractures from non-battle injuries in deployed areas. In contrast, combat injuries often involve a higher overall trauma burden; extreme transfusion requirements; extensive soft tissue injuries; associated arterial injuries; multi-level limb trauma; and occur in remote locations. This results in fifteen percent of all military orthopaedic trauma casualties requiring at least one prophylactic or therapeutic fasciotomy.[6]

Recent research indicates proper detection of Compartment Syndrome (CS) is lifesaving and delay in diagnosis can be lethal.[7] The operational definition of CS is a clinical syndrome wherein high pressure within a myofascial space reduces perfusion and decreases tissue viability. Therapeutic fasciotomy is indicated for established CS, and prophylactic fasciotomy is indicated when there is a substantial risk of compartment syndrome.[8-10] Fasciotomy during the lag phase between injury and syndrome onset is prophylactic. Early detection is challenging, so prophylactic fasciotomy should be routine when compartment syndrome is likely. Prophylactic fasciotomy is most commonly indicated in patients with certain “at risk” fractures and in patients with prolonged ischemia or following limb reperfusion. Injury, treatment, and casualty variables affect risk (Tables 1 and 3) and may be interrelated.[7-13] The difficulties associated with monitoring a patient’s physical exam during lengthy periods of transport must be considered in the decision to perform prophylactic fasciotomy, along with the inability to intervene surgically during Aeromedical Evacuation (AE).

The main factors are limb injury severity (particularly vessel injuries) and overall casualty injury severity (particularly shock) with a lesser factor being aggressive resuscitation (particularly >5 liters of crystalloid). Tissue edema and subsequent swelling due to injury maximizes in 1 to 2 days. Additional swelling from post-injury ischemia reperfusion (e.g., revascularization, shock, and tourniquet use) appears to delay the maximal time of limb swelling further; perhaps to 2 to 5 days post injury. High altitude (including normal AE aircraft cabin pressure), in and of itself, is not a contributor to compartment syndrome (Ritenour, et al). Compartment syndrome can lead to significant morbidity and mortality (Table 2). Surveys indicate surgeons with more training and experience, are more willing to perform fasciotomy. Once the decision is made to perform a prophylactic or therapeutic fasciotomy, a complete fasciotomy must be performed.[14] There is evidence to support complete compartment release by full-length skin and fascial incisions as being superior to limited fasciotomy. Incomplete fasciotomy, a clearly preventable problem, risks worsened patient morbidity, mortality, and functional outcome.

EVALUATION

Tissue edema due to injury peaks at 24-48 hours, but vigilance should be maintained in the first week post-trauma, especially in cases requiring sequential surgical procedures, ongoing resuscitation, or in the presence of ischemia-reperfusion. The signs and symptoms of CS are the classic “5 P’s” which include: pain; palpably tense muscle compartments; paralysis; paresthesia’s or sensory deficit; and pulselessness.[2] Pain out of proportion to the injury or with passive stretch of a muscle group is the most important clinical finding, but is often obscured in combat casualties due to altered mental status, heavy sedation, and mechanical ventilation. Palpably tense compartments are thought to be specific but not sensitive; this clinical finding is also highly subjective. Paralysis and paresthesias are less useful acutely as they can also result from direct neural trauma. Pulselessness is a late

and ominous sign in civilian CS, but occurs more commonly in combat injuries, sometimes within minutes of an arterial injury or an expanding hematoma. The most common compartment syndrome is in the anterior leg.[1-2] About 45% of all compartment syndromes are caused by tibia fracture. Open fractures, even with traumatic fasciotomy, have higher CS rates than closed fractures because they are more severe, with more swelling and more often injured arteries. The most commonly missed compartment syndromes are in the anterior and deep posterior compartments of the leg. The most commonly incompletely released compartments are also in the leg.[1]

Pressure measurement has significant limitations and is not recommended for routine use in theatre. Emerging technologies, such as ultrafiltration catheters, may eventually allow continuous pressure monitoring while providing pressure relief by suctioning interstitial fluid.[15] When monitoring patients for the development of CS, serial clinical examinations are repeated hourly when risk is high and less frequently when low. Provider experience and training improves detection. Documentation is important for later providers and performance improvement.

In one study, burns sustained in combat have been associated with an increased fasciotomy rate.[7] In the absence of crush injury, fracture, multiple trauma, over-resuscitation, electrical injury, or similar indications, prophylactic fasciotomy on burned extremities may increase morbidity and mortality and are not indicated. (For additional information on escharotomy and fasciotomy in the management of patients with extremity burns, see JTS Burn Care CPG).[16]

TREATMENT

OPERATIVE INTERVENTION

CS requires immediate operative intervention. Once intra-compartmental pressure reaches a critical threshold, only surgical treatment can interrupt the cascade of events leading to ischemia and tissue necrosis. This should be accomplished as soon as possible, as irreversible tissue necrosis occurs within a few hours. Delayed or incomplete compartment release has been associated with increased mortality and need for amputation in military casualties.[6] Therapeutic fasciotomy is performed for established compartment syndrome while prophylactic fasciotomy is performed for limbs at risk of developing CS.[8-10] The decision to proceed with prophylactic fasciotomy is based on the pattern of extremity injury, the patient's physiological profile, and operational considerations. We recommend that any limb at risk of CS in an austere location, particularly when AE is anticipated or after extremity vascular repair, should undergo prophylactic fasciotomy when they reach a fixed surgical facility. This avoids missed compartment syndrome or delayed compartment release, especially during times of high battle rhythm. The difficulties associated with monitoring a patient's physical exam during lengthy periods of transport must be considered in the decision to perform prophylactic fasciotomy, along with the inability to intervene during AE. High altitude (including normal AE aircraft cabin pressure), in and of itself, is not a contributor to compartment syndrome.[17,18]

DELAYED EVACUATION

Occasionally, casualties present with a compartment syndrome of prolonged duration (> 12 hours) due to delayed evacuation. This situation is associated with markedly increased risk of complications, including death and infection.[12] These casualties may be best treated with appropriate resuscitation, urine alkalization, mannitol use, and intensive support.[19] Such conservative care has led to better outcomes than fasciotomy in casualties with closed injuries with mechanically crushed muscle.[12] Therefore, compartment syndromes with greater than 12 hours of warm ischemia with nonviable muscle should not routinely undergo fasciotomy.[19] The role of amputation is currently unclear in this situation.

FASCIOTOMY

Once the decision is made to perform compartment release, a complete fasciotomy must be performed.[14,20] This involves releasing all compartments in the affected anatomic region over their full length. In the calf/leg, the anterior, lateral, superficial posterior and deep compartments must be released through full length incisions. Although a one-incision approach is possible in expert hands, we feel that a two incision technique should remain the standard of care in combat.[21,22] A frequent error by inexperienced surgeons is not releasing the deep posterior compartment of the calf/leg. In the forearm, the superficial and deep volar compartments must be released through an incision that extends from the lacertus fibrosus to the carpal tunnel. The dorsal compartment, when involved, is released through a separate incision. Incomplete fasciotomy can be secondary to failure to release a specific compartment or to short fascial incisions. The most commonly missed compartment syndromes are the anterior and deep posterior compartments of the calf/leg.[7] The most common incompletely released compartments are also in the calf/leg.[7] Incomplete fasciotomy is associated with worse outcomes; fortunately, improved surgical education has been shown to decrease the rate of fasciotomy requiring revision.[7,23] There is no reported experience with fasciotomy performed by non-surgeons in austere locations. We would caution that attempting this procedure outside of an operating room setting is fraught with pitfalls, including uncontrollable bleeding and iatrogenic neurovascular injury. Wound vacuum dressings or laced vessel loops are both acceptable methods of initially covering the surgical wounds.

The common reasons for incomplete calf fasciotomy are:

- Improper identification of the septum dividing the anterior and lateral compartments. This can be avoided by making an initial transverse incision in the fascia overlying the septum, then deliberately opening the anterior and lateral compartments separately, creating a so called “H” incision.
- Incomplete development of the deep posterior compartment release by not deliberately taking the soleus muscle fibers off the posterior tibia. If performed correctly, the neuro-vascular bundle should be exposed in a fully decompressed deep posterior compartment.
- Fascial incisions are too short and do not cover the entire extent of the fascial compartment, either at the knee or ankle levels.

Passive stretch pain (e.g., ankle dorsiflexion), palpation of muscles for tenseness and pulse quality combined with an index of suspicion makes up the mainstay for clinical evaluation. Pressure monitoring by manometer does not reliably diagnose CS in theater, so the diagnosis remains a clinical, not a technological diagnosis. Since there is currently no sensitive or specific technique for establishing the diagnosis of compartment syndrome, a fasciotomy should be considered in a patient with significant mechanism of injury and clinical findings suspicious for compartment syndrome.

TREATMENT OF FOOT CS

Fasciotomy for treatment of CS of the foot remains controversial. While surgical release is generally supported in the literature, the sequelae of foot fasciotomy can, in many instances, result in more severe sequelae (infection, skin grafting, difficulty with shoe wear) than result from compartment syndrome itself (claw toe deformity). The surgeon must, therefore, carefully weigh the advantages and disadvantages prior to performing foot fasciotomies.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

- All patients diagnosed with compartment syndrome
- All patients with limb AIS ≥ 3 or tourniquet time > 2 hrs

INTENT (EXPECTED OUTCOMES)

1. Compartment syndrome is diagnosed and treated prior to tissue necrosis.
2. When fasciotomy is indicated, a complete fasciotomy is performed.
3. Tourniquet times are documented.
4. The use of prophylactic fasciotomy is minimized.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients diagnosed with compartment syndrome who receive fasciotomy performed at the same role of care (or have reason for delay documented).
2. Number and percentage of patients undergoing fasciotomy who require debridement of necrotic muscle in the affected limb.
3. Number and percentage of patients with tourniquet placed who have tourniquet times (placement and removal) documented.
4. Number and percentage of patients who undergo fasciotomy who do not have a diagnosis of compartment syndrome.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DODTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

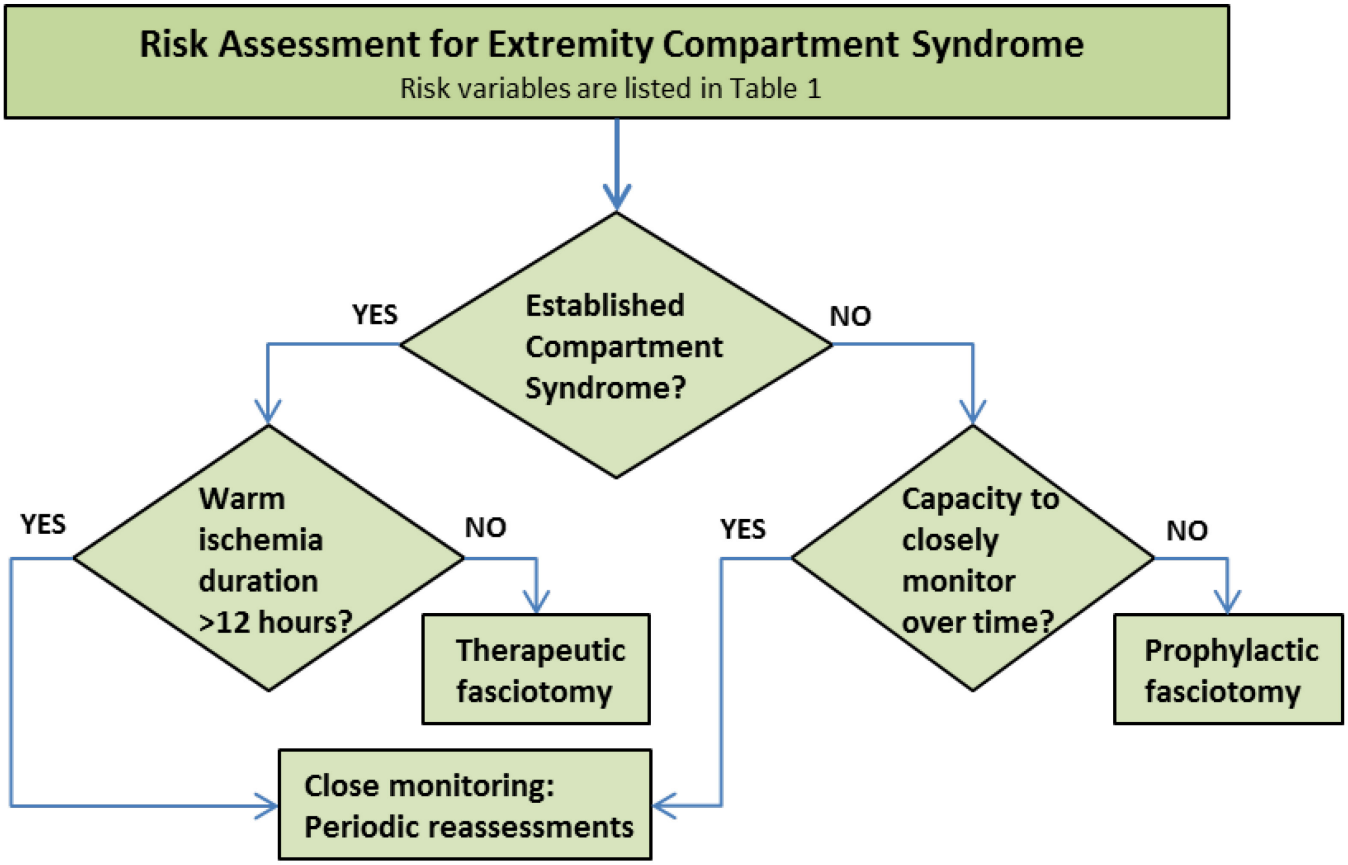
APPENDIX A: RISKS

Table 1. Risks for Acute Traumatic Compartment Syndrome	
Decreased Compartment Volume	• Tight cast or dressing, closure of prior fasciotomy, excess traction • External limb compression or crush particularly in obtunded or incapacitated casualty • Frostbite, burns or electric injury (may include escharotomy)
Increased Compartment Contents	• Edema accumulation: embolism, intravascular thrombosis, replantation, venous tourniquet, injections, extravasation, infiltration, ergotamine ingestion, ischemia-reperfusion, swelling, artery injury or spasm, revascularization procedures, prolonged arterial tourniquet use, shock hypoperfusion, angiography and catheterization, limbs positioned well above heart, mal-positioned joints (ankle dorsiflexion,) or stretched muscles • Prolonged immobilization and limb compression particularly with obtunded or drugged casualty, some surgical positioning • Hemorrhage, hemophilia, coagulopathy, anticoagulation, vessel injury • Large volume crystalloid resuscitation • Fractures particularly tibia fractures in adults, supracondylar humerus fractures in children displaced, comminuted, or open fractures increase hemorrhage, swelling, and CS risk • Popliteal cyst, long leg brace

Table 2. Morbidity Risk and Sequelae of Compartment Syndrome and Fasciotomy	
Potential Morbidity: Compartment Syndrome and Early Fasciotomy	• Skin scar, scaly skin, ulceration, tethered tendons • Postoperative arterial or graft thrombosis, thromboembolic disease • Wound infection, non-healing fasciotomy wounds • Limb swelling or chronic edema, shape change of limb, muscle hernia • Pain, paresis or paralysis, paresthesia • Coverage challenge: primary closure, delayed primary closure, skin graft, flap • Possible repair of arterial injury worsening ischemia-reperfusion injury
Potential Sequelae List: Compartment Syndrome with Late or Incomplete Fasciotomy	• Mortality, sepsis, multi-organ failure, acute kidney failure, • Myonecrosis, myoglobinemia, myoglobinuria, or rhabdomyolysis • Paresis or paralysis • Stiffness or contracture • Limb amputation, tissue loss, e.g., muscle debridement

APPENDIX B: ALGORITHM FOR CLINICAL DECISION MAKING ON COMPARTMENT SYNDROME IN A DEPLOYED SETTING



APPENDIX C: COMPARTMENT SYNDROME HEALTHCARE RECORD DATA

Table 3. Healthcare Record Data in the Setting of Compartment Syndrome During War
• Was the fasciotomy prophylactic (compartment syndrome absent) or therapeutic (compartment syndrome present)?
• When was the fasciotomy indicated and when was the injury?
• When was the procedure (to determine treatment lag)?
• Was the casualty able to be followed closely? If so, what was the clinical course? Was the casualty alert, intubated, or head injured?
• Was there a nerve injury or nerve block/regional anesthetic?
• What was the injury or risk factors (e.g., ischemia-reperfusion) that indicated the procedure?
• What are the sources of ischemia-reperfusion in the injury and care of this case?
• Associated injuries altering risk of compartment syndrome: shock, occult hypoperfusion, hypoxia, nerve dysfunction, impaired, obtunded, or uncooperative casualty, arterial injury or ischemia, fractures with soft tissue injury, over-resuscitation syndrome, coagulopathies (including hemophilia, etc.), hematoma formation, crush injury, capillary leak syndrome, and prolonged compression.
• What were the surgical findings and muscle compartment response to the procedure?
• What was the technique (dermotomy, fasciotomy, surgical approach, length of fasciotomy)?
• Was there retinaculotomy or epimysiotomy? List names of all compartments released.
• What delimited the fasciotomy extent, e.g., anterior leg fascia goes from the proximal tibial crest near Gerdy's tubercle to the anterior ankle extensor retinaculum (crural ligament)?
• List associated procedures: debridement, irrigation, fracture fixation, etc.
• Planned care: staged? Closure, repeat debridement, delayed primary, skin graft, or flap

APPENDIX D: COMPARTMENT DATA SHEET

Table 4. Data Sheet: Compartment Names, Main Muscles, and Diagnosis and Procedure Codes

Compartment	Main muscle(s)	Left or Right	Wound Notes, Compartment Syndrome (CS), Diagnoses, Indications, & Findings	Procedure(s) and Tissue Response to Procedure
			958.91: traumatic CS of upper extremity 958.92: traumatic CS of lower extremity 958.99: traumatic CS of other sites 958.90: CS, unspecified Prophylactic (CS absent) or therapeutic (CS present). Artery, vein, clot, & hematoma findings in compartment on exploration	83.12: fasciotomy of hand 83.14: fasciotomy, division of fascia 83.09: incision of fascia 86.09: escharotomy dermotomy, epimysiotomy Response: muscles bulged through fasciotomy, no bulge, pulse returned after absence

APPENDIX E: OPERATIVE NOTE TEMPLATE

Table 5. Operative Note Template for Dictation, Surgical Planning, or Data Collection

1. Patient	2. Surgeon
3. Date of Surgery	4. Anesthesia
5. EBL:	6. Tubes
7. Specimens	8. Complications
9. Implants, Devices	
10. Indication for operation: a. Established compartment syndrome (therapeutic) b. Risk of compartment syndrome developing (prophylactic)	
11. Preoperative wound appearance: a. Size (volume of damaged tissue: large surgeon hand ~500ml) b. Depth, location, contamination material or matter	
12. Preoperative imaging findings: a. Soft tissue injury seen & fracture	
13. Examination under anesthesia, fluoroscopy, and surgical exploration findings: a. Distal pulse status b. Wound size, depth, location, contamination, materials or matter; burn eschar location and depth c. Vessel status, pulse, limb perfusion, capillary refill, congestion, edema, color of skin, warmth d. Clot presence, intravascular or extra vascular site, size (volume), location e. Hematoma presence f. Compartment hardness: soft, hard i. Epimysiotomy (if done by muscle name or compartment if known) ii. Retinaculotomy (if done by name, e.g., partial proximal ankle extensor iii. Retinaculotomy extended from anterior leg compartment fasciotomy iv. Result of fasciotomy and procedure (distal perfusion and pulse; gap in fasciotomy edges on release in cm; bulging out of muscles in compartment) v. Compartments soft or hard vi. Muscle color, consistency, contractility, capacity to bleed	
14. Patient condition, status, disposition and plan.	
15. Key note for air evacuation: “Patient has been monitored for X hours after injury/surgery and has not had progression of signs or symptoms of compartment syndrome.”	

APPENDIX F: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Acute Respiratory Failure (CPG ID: 06)

This CPG describes the associated risk factors, diagnosis, and management of Acute Respiratory Distress Syndrome (ARDS) in combat casualties in the forward deployed environment and the resources available for safe Aeromedical transport of these patients.

BACKGROUND

Patients with multiple injuries are known to develop lung injury[1] which can result in long-term disability or even death.[2] A recent review of combat casualty deaths following admission to a hospital demonstrated that 8% of potentially preventable deaths are from multi-organ failure which includes ARDS.[3] The purpose of this guideline is to review the diagnostic criteria for ARDS, to describe the frequency of this problem in combat casualties, and to recommend a series of management strategies to permit safe aeromedical evacuation of these patients.

Respiratory failure has been observed in combat casualties for over a century. Some degree of ARDS occurs in between 26% and 33% of combat casualties.[1,4,5] In a review of the DoD Trauma Registry (DoDTR), 152 patients with ARDS were identified over a 7 year period.[6] Independent risk factors for ARDS included female gender, shock or tachycardia on presentation, and severe injury (Military Injury Severity Score (mISS) ≥25). Patients with ARDS had a significantly increased risk of death as compared to intubated controls (12.8% vs. 5.9%, Odds Ratio 1.99, 95% confidence interval [1.12, 3.52], p=0.02). Further analysis of this population identified that increased crystalloid infusion and Fresh Frozen Plasma (FFP) transfusion independently predicted ARDS.[7]

DEFINITIONS

- ARDS develops as a result of both direct and indirect injury to the lungs. Common causes of ARDS following a direct injury include pneumonia or gastric aspiration. In combat casualties, direct insults such as pulmonary contusion, inhalation injury, and fat emboli may lead to ARDS. ARDS from indirect lung injury can occur in patients who receive multiple transfusions, who develop septic shock, or in those with severe acute pancreatitis.

- Cardiac failure or fluid overload must be ruled out when considering the diagnosis of ARDS. Several other disease processes can also mimic ARDS. Patients with these conditions will benefit from lung-protective ventilator management but may require disease-specific interventions as well. Examples include Acute Eosinophilic Pneumonia (AEP), Acute Interstitial Pneumonitis (AIP), Bronchiolitis Obliterans Organizing Pneumonia (BOOP), and Diffuse Alveolar Hemorrhage (DAH).[8]

- The definition of ARDS was updated in 2012. The new Berlin definition of ARDS reflects a range of severity from mild to moderate to severe, defines "acute onset" as within one week and specifies the need for Positive End Expiratory Pressure (PEEP) ≥5 cm H_2O.[9] The original American-European Consensus Conference (AECC) definition of ARDS which also included Acute Lung Injury (ALI)[10] is less practical; so this CPG will refer to the new Berlin definition. Timing of ARDS must occur within one week of a known clinical insult described above, or must be in the context of new or worsening respiratory symptoms. On chest imaging (CXR or CT scan), bilateral opacities must be present which are not fully explained by pulmonary edema, effusions/hemothorax, lobar collapse, or pulmonary nodules. If the above criteria are met, the degree of hypoxemia with a PEEP or Continuous Positive Airway Pressure (CPAP) of at least 5 cm H_2O determines the severity of ARDS.

    1. **Mild ARDS** = PaO_2 to FiO_2 ratio (P:F) of > 200 and ≤ 300.
    2. **Moderate ARDS** = P:F of >100 and ≤ 200.
    3. **Severe ARDS** = P:F of ≤ 100.

- The diagnosis of ARDS is typically made in patients who have respiratory failure that requires intubation and mechanical ventilation.

DIAGNOSIS

Patients suspected of having ARDS on the basis of CXR findings and ventilator settings should have their diagnosis confirmed by following the below guidance.

1. Verify that the patient is likely to have respiratory failure from either a direct or indirect pulmonary injury or the need for mechanical ventilation support.
2. Consider diagnoses which can mimic ARDS as described above.
3. Obtain a good quality anteroposterior upright CXR and look for diffuse infiltrates. Consider a chest CT if this imaging modality is available and the patient is stable for transport to CT.
4. If cardiogenic pulmonary edema and/or fluid overload cannot be fully excluded as the cause of or a contributing factor to the patient's respiratory failure, consider placing a central venous pressure catheter and obtain a trans-thoracic echocardiogram if possible.[11,12]
5. Place the patient on volume- or pressure-control ventilation.
    a. Tidal volume (V_T) approximately 6-8 mL/kg using Predicted Body Weight (PBW), see ARDSNet Card in Appendix B) targeting a plateau pressure (P_{PLAT}) ≤ 30 cm H_2O or if using a pressure control mode of ventilation, set the inspiratory pressure to 30-35 cm H_2O and then decrease it gradually to achieve a V_T of 6-8 mL/kg.
    b. Set the respiratory rate between 6 and 35 and adjust to achieve a pH≥7.3.
    c. Set PEEP (minimum 5 cm H_2O) and FiO_2 according to the ARDSNet table[23] to achieve a SpO_2 of 88-95% (PaO_2 of 55-80 mmHg). Allow the patient's gas exchange to equilibrate for 30 minutes and then draw an ABG to calculate the patient's P:F ratio.

If ARDS is confirmed, document the grade (mild, moderate, severe) in the patient's record with the diagnostic criteria used. A recent study further demonstrated that Age-Adjusted Oxygenation Index (AOI) accurately predicts prognosis in patients with ARDS.[13] Traditionally, the Oxygenation Index (OI) is calculated as where MAP is mean airway pressure. This study relied on the ARDSNet database which recorded P_{PLAT} rather than MAP; so the AOI was calculated as $(\frac{100\times P_{PLAT}}{P:F}) + Age$. These authors found that an AOI of 80-99 in the first four days of ARDS was associated with 50% mortality.

Pediatric trauma patients are also at risk for development of ARDS.[14] While there are many similarities in the pathophysiology of ARDS in adults and children, recent literature has supported a slightly different approach with the diagnostic criteria used in pediatric ARDS.[15,16] Similar to the Berlin criteria for adults, ARDS in children requires respiratory failure not explained by cardiac failure or volume overload. However, instead of utilization of a P:F ratio, recent recommendations have been made to utilize OI to grade severity of ARDS in the pediatric population. As above, OI can be calculated as $(\frac{100\times MAP}{P:F})$. Mild ARDS can be defined as an OI of 4 to <8, moderate ARDS defined as an OI of 8 to <16 and severe ARDS defined as an OI ≥16.[15,16]

MANAGEMENT

The management of patients with ARDS should safely support gas exchange without further injuring the patient's lungs.[17] In fact, using a lung-protective ventilator strategy in *all* intubated patients appears to improve clinical outcomes.[18–20] Providers must also recognize that there are also some limitations imposed by the transport ventilators and that the patient's PaO_2 will always decrease during aeromedical transport.[21,22]

In patients with ARDS, the goal is to limit barotrauma (P_{PLAT}≤30 cm H_2O or peak inspiratory pressure, PIP≤35 cm H_2O if PPLAT cannot be measured), volutrauma (V_T 6-8 mL/kg PBW) and atelectrauma (moderate to high PEEP).[17] Goals should include an SpO_2≥88-95% and a pH≥7.3 (in traumatic brain injury, this pH goal should be met with the $PaCO_2$ maintained at 35-40 mm Hg).

Early consultation with an intensivist is encouraged for all patients with moderate to severe ARDS. Military physician-to-physician consultation can be obtained by contacting Landstuhl Regional Medical Center (LRMC) at DSN 314-486-7141 or San Antonio Military Medical Center (SAMMC) at DSN 312-429-BURN (2876).

For Role 3 patient management, see Appendix A.

VENTILATOR AND GAS EXCHANGE MANAGEMENT

Lung-Protective Ventilation Settings

Once ARDS has been diagnosed, the patient should be placed on lung-protective ventilation settings according to the ARDSNet ventilator management card.[23] The patient's PBW is determined by measuring the patient's height and then using the appropriate gender-based calculation. Note there are two different PEEP tables, one with a lower PEEP and higher FiO_2 and the other with a higher PEEP and lower FiO_2. Either is acceptable, but meta-analysis suggests a trend towards improved survival using the high PEEP table in patients with moderate to severe ARDS by modern criteria.[24] In all cases, the "driving pressure" (P_{PLAT} – PEEP) should be minimized to optimize the patient's chances of survival.[25] During the initial management, a V_T of 8 mL/kg may be used, but this should be decreased to 6 mL/kg within 2-4 hours. If the P_{PLAT} remains above 30 cm H_2O, the tidal volume can be further reduced to 4 mL/kg so long as there is evidence of adequate oxygen delivery to peripheral tissues (normal lactate and base deficit).[26] Other modes of ventilation besides volume-assist-control can be used, but this should be at the discretion of an intensivist experienced in the management of ARDS.

Rescue Oxygenation Therapies

Advanced therapies for ARDS patients are limited in an austere environment. Low-level recruitment maneuvers performed by holding 40 cm H_2O pressure for 40 seconds can be performed by the patient's provider, but the team should be prepared to manage unstable hemodynamics due to decreased venous return. Other measures such as inhaled Nitric Oxide (iNO) or inhaled prostacyclin (Flolan) are not typically available in Role 3 facilities. Advanced rescue ventilator modes such as inverse ratio ventilation or Airway Pressure Release Ventilation (APRV) should be utilized under the supervision of an experienced intensivist.

Extracorporeal Life Support

Early consideration for Veno-Venous Extracorporeal Life Support (vvECLS) is vital in patients who are failing attempts at lung-protective ventilation.[27] If gas exchange and perfusion goals are not met after 12 hours of lung-protective ventilation and the patient has been paralyzed and proned, then extracorporeal support should be considered. Additionally, transport of patients who are supported with vvECLS may be safer and easier if an extracorporeal transport team is available. (See *Transport of ARDS patients* below).

Indications for initiating Extracorporeal Membrane Oxygenation (ECMO) for respiratory failure include:

1. P:F ration <100 or plateau pressures > 30cm H_2O despite optimal ventilator management.
2. Respiratory acidosis with pCO_2>70 and a pH <7.25 despite optimal ventilator management.
3. Initiation of ARDS rescue therapies (PEEP>15, prone positioning, High Frequency Oscillation (HFOC), iNO, prolonged paralysis)
4. Respiratory failure associated with significant barotrauma needed for ventilator support.

ECMO consultation is available 24 hours a day and can be coordinated through the Institute of Surgical Research (ISR) Burn Unit (210-222-BURN). Due to the dramatic sequelae of acute respiratory failure and the time required to generate a potential ECMO transport team, **early notification is paramount**. Early consultation with the ECMO team is essential, even if it is **prior to 12 hours of respiratory failure.**

NEUROMUSCULAR BLOCKADE

If a patient has severe or rapidly worsening ARDS, a short course (48 hours) of neuromuscular blockade may facilitate continued use of Lung Protective Ventilation (LPV) while eliminating such problems as ventilator dyssynchrony.[28] This strategy carries a survival benefit in patients with confirmed ARDS when used early in the course of disease (within 48 hours). Cisatricurium (Nimbex®) minimizes the risk of ICU-related neuropathy or myelopathy, as compared to other neuromuscular blockers, and does not require dose adjustment in renal or hepatic insufficiency. Thus, cisatricurium is the preferred neuromuscular blocking agent in patients with ARDS.[29, 30]

PRONE POSITIONING

If the patient's disease is primarily in the lower lobes (based on CXR or CT findings), a trial of prone positioning for 2–6 hours should be performed.[31] If the patient's gas exchange improves, continue the proning therapy. A recent study of patients with moderate to severe ARDS (P:F <150) demonstrated a mortality benefit to proning for 16 hours/day.[32] This is best done by an experienced team able to avoid tube/line dislodgment during the proning maneuver, and may not be practical in the deployed or austere setting. The EKG electrodes are placed on the patient's back and the eyes are taped shut. This approach is best implemented in the setting of a proning protocol which includes indications and contraindications, a pre-proning checklist, and a description of nursing care of the proned patient.

FLUID MANAGEMENT

Patients with ARDS in the setting of a positive fluid balance have an increased mortality.[33] Thus, early and aggressive limitation of unnecessary volume infusion is encouraged by eliminating any "maintenance IV fluid," maximally concentrating all necessary drips, and converting IV medications to enteral. If the patient's hemodynamics can tolerate diuresis, this should be pushed aggressively.[34] In the setting of hemodynamic compromise, attempts should be made to minimize volume and be judicious with any trials of diuresis. Some Role 3 facilities are equipped with Continuous Renal Replacement Therapy (CRRT) which can also be used to eliminate excess intravascular volume in the setting of poor renal function under the direction of an intensivist or nephrologist experienced in this therapy (See JTS *Hyperkalemia and Dialysis in the Deployed Setting* CPG[35]). If the patient is hypoproteinemic (i.e. total protein < 6 g/dL), albumin 25 g IV every 8 hours (100 mL 25% albumin) combined with diuresis for 3-5 days has been demonstrated to improve oxygenation and diuresis in two prospective randomized studies in patients with ARDS. The goals of therapy include a CVP < 4 mmHg with evidence of effective circulation by exam (warm, no mottling and capillary refill < 2 s) and adequate urine output (≥ 0.5 mL/kg/hr).[12]

BLOOD PRODUCT TRANSFUSIONS

Blood products carry a risk of initiating or exacerbating respiratory failure.[36-39] In a recent study of the DoDTR, moderate numbers of Red Blood Cell (RBC) transfusions (2-14) increased the risk of ARDS. Furthermore, each unit of additional plasma transfused increased the risk of ARDS in intubated combat casualties by 7%.[36] Similar findings have also been demonstrated in the civilian trauma population.[39] Thus, it is imperative to balance the benefits of Damage Control Resuscitation (DCR) against the risk of ARDS. If the patient is bleeding and needs blood volume replaced, blood products should not be withheld. Furthermore, in patients with severe ARDS refractory to maximal ventilator support, transfusion of additional RBCs may be necessary to sustain adequate oxygen delivery. On the other hand, a patient who is no longer bleeding who has asymptomatic anemia[40] or a

mildly elevated International Normalized Ratio (INR) with a normal thromboelastogram or rotational thromboelastogram likely does not need additional blood products.

CORTICOSTEROID ADMINISTRATION

Intravenous steroids have generally shown no benefit in the initial treatment of ARDS.[41] However, initiation of low to moderate-dose corticosteroids in highly-select patients can improve pulmonary mechanics and reduce ventilator and ICU days without increasing complications including infections and neuropathy/myelopathy.[42,43] This select population consists primarily of those with "late-phase" or "prolonged" ARDS, defined as duration of ≥7 days. The ARDSNet Late Steroid Rescue Study Trial demonstrated a potential benefit of steroids in the subgroup of patients with ARDS duration between 7-13 days, but potential harm of steroids when administered to patients who were at ≥14 days of duration. In patients without contraindications, the recommended regimen is methylprednisolone 2 mg/kg IV x1 followed by an infusion of 2 mg/kg/day (can be divided into every 6 hour doses) for 14 days (or for the duration of intubation, whichever is shorter). The infusion can then be tapered over 7-21 days based on clinical judgment. If steroids have not been initiated within two weeks of an ARDS diagnosis, they should be avoided due to an increased mortality with delayed therapy.[44] Of note, AEP can masquerade as ARDS and has been described in deployed military members who recently started smoking.[45] AEP is highly sensitive to steroid therapy; so it is very important to correctly diagnose AEP from the more common ARDS.

NUTRITION AND VENOUS THROMBOEMBOLISM PROPHYLAXIS

Patients with ARDS receive nutritional support (See JTS *Nutritional Support Using Enteral and Parenteral Methods* CPG).[46] Enteral feeds are preferred if the gastrointestinal system is functional. Consideration should be given to positioning a naso-jejunal feeding tube for this purpose; a naso-gastric feeding tube can also be used if a feeding tube cannot be advanced through the pylorus. Stress ulcer prophylaxis is recommended in critically ill intubated patients, and all patients with ARDS should be considered for chemical Venous Thromboembolism (VTE) prophylaxis once adequate hemostasis has been achieved.

SEDATION MANAGEMENT AND PHYSICAL THERAPY

The major long-term morbidity of ARDS is neurologic and/or musculoskeletal disability related to prolonged inactivity.[29,30] Consequently, at the earliest possible time, patients should undergo a daily awakening trial ("sedation holiday")[47] and should be started on an aggressive program of early mobilization. This consists of a staged approach even while intubated, beginning with passive range of motion (performed multiple times daily by providers, nurses, therapists, co-workers, and family) and then progressing to sitting up at the side of the bed, moving from bed to chair, and ambulating with assistance.[48, 49]

ARDS IN PEDIATRIC PATIENTS

Ventilator management of ARDS in children is similar to their adult counterparts with a goal to limit ventilator-induced lung injury. Additionally, adjunctive and rescue measures are also similar in pediatric ARDS patients.[16]

TRANSPORT OF ARDS PATIENTS

CRITICAL CARE AIR TRANSPORT TEAM (CCATT) CAPABILITIES

Intubated U.S. military patients are routinely transported out of theater by the Critical Care Air Transport Team (CCATT).[50–52] From October 2001 to May 2006, these made up 1,265 of 1,995 (63%) of all CCATT patients.[53] The decision to transport a patient with ARDS should be made jointly with the theater CCATT Director and the validating flight surgeon, the on-site CCATT physician, and the Role 3 Chief of Trauma and/or ICU Director.

Considerations should include the severity of the patient's respiratory failure, the trajectory of that respiratory failure (improving or worsening), and the experience of the team.[22]

U.S. Air Force CCATT has both the Impact 731™ (Zoll Medical Corporation., Chelmford, MA) ventilator and the LTV 1000™ (CareFusion., Yorba Linda, California) ventilator for use in transport.[54] The Impact 731 operates in volume control, pressure control, SIMV, and CPAP with and without pressure support. Up to 100% O_2 can be applied as can PEEP of up to 25 cm H_2O. Flow rates range from 0 to 100 L/min at 40 cm H_2O. Peak inspiratory pressures range from 10 to 80 cm H_2O. Inverse ratio ventilation is not possible with the Impact 731.

ADVANCED CRITICAL CARE EVACUATION TEAM (ACCET) CAPABILITIES

In 2012, SAMMC established an ECLS team and now offers long-range transport of patients with severe ARDS with or without ECLS. The team consists of a medical/pulmonary critical care physician, a surgical intensivist, an ICU nurse, and a respiratory therapist. Advanced therapies used by this team include high frequency percussive ventilator (Percussionaire VDR-4), inhaled prostacyclin (Flolan), and ECLS for the management of patients with moderate to severe ARDS who could not otherwise be safely transported.[55–58]

Indications for requesting an ACCET for transport to the U.S. include the following:

- PaO_2: FiO_2 < 100 .
- Inhalation injury.
- FiO_2 > 0.7 or pH < 7.25 on lung-protective ventilation.
- PEEP > 15 cm H_2O w/ PPLAT > 30 cm H_2O.
- Severe brain injury with $PaCO_2$ > 40 mmHg on a transport ventilator.
- Cardiogenic shock refractory to maximal medical therapy.
- Anatomic derangement (e.g., Bronchopleural fistula, pneumonectomy).
- Use of advanced ventilator modes such as APRV.
- Acute Pulmonary Embolism (PE) with cardiac arrest or with persistent hypoxemia.
- Multi-system organ failure (e.g., ARDS + Renal Failure).

ACCET team members are specifically trained in the indications for and the use of these modalities which have all been appropriately vetted through the combat casualty care and transport communities.

- High-frequency percussive ventilation can be helpful in cases of purulent pneumonia or inhalation injury by mobilizing secretions while affording safe gas exchange.[59]

- ECLS is used for adult respiratory failure with good outcomes as demonstrated in recent series using modern equipment.[60-62] Most adult ECLS is Veno-Venous which can be performed through either single site internal jugular (IJ) vein cannulation, combined IJ/femoral vein (FV) or dual-FV cannulation. Systemic heparin should be administered once surgical bleeding has been controlled. This approach has been used safely in trauma patients both in the U.S. and in Germany, including patients with Traumatic Brain Injury (TBI).[62–65]

- ACCET transports should be initiated by the local Chief of Trauma and/or ICU Director by contacting U.S. Transportation Command (TRANSCOM) through the normal intertheater evacuation procedure. This will facilitate timely activation of the appropriate team. Physician-to-physician consultation can also be obtained by contacting LRMC at DSN 314-486-7141 or SAMMC at DSN 312-429-BURN (2876). Early consultation and ECLS team activation are always encouraged.

- From Nov 2005 – Mar 2007, 524 intubated patients were transported via CCATT. Of these, five were moved by the LRMC ALRT which had been called on a total of 11 patients. Of the five ALRT patients requiring advanced support modes, four survived to hospital discharge.[66] Furthermore, of 10 U.S. combat casualties transported on either Pumpless Extracorporeal Lung Assist (PECLA) or ECLS, nine survived to hospital discharge.[55] These data underscore the importance of utilizing available resources for transporting these tenuous patients to definitive care.

OUTCOMES

In a general civilian population, the in-hospital mortality in patients with ARDS remains upwards of 40%[67] and the 5-year mortality is approximately 60%.[68] For trauma patients, ARDS increases morbidity[69] and may increase mortality as well,[70] although there is some inconsistency in the current civilian literature.[71] However, ARDS is an independent risk factor for death in combat casualties as noted above. To mitigate this risk, early LPV should be implemented along with minimizing unnecessary IV infusions, eliminating unnecessary blood product transfusions, and implementation of an aggressive physical therapy regimen if possible. Early activation of the ACCET evacuation system should also be considered.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients who receive mechanical ventilation

INTENT (EXPECTED OUTCOMES)

1. Patients with Acute Respiratory Distress Syndrome (ARDS) are treated with lung protective ventilation.
2. Advanced airway support team consultation occurs within 4 hours when criteria are met (ex. PaO2:FiO2 < 100, FiO2> 70%, PEEP > 15 cmH2O with Pplat > 30 cm H2O, severe TBI with PaCO2 > 40 mmHg, etc).

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients diagnosed with ARDS who receive initial tidal volume 6-8 mL/kg.
2. Number and percentage of patients who have advance airway support team consultation within 4 hours when criteria are met (ex. PaO2:FiO2 < 100, FiO2> 70%, PEEP > 15 cmH2O with Pplat > 30 cm H2O, severe TBI with PaCO2 > 40 mmHg, etc) and patient is eligible for evacuation (US or coalition casualties).

DATA SOURCE

- Patient Record.
- Department of Defense Trauma Registry (DoDTR).

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

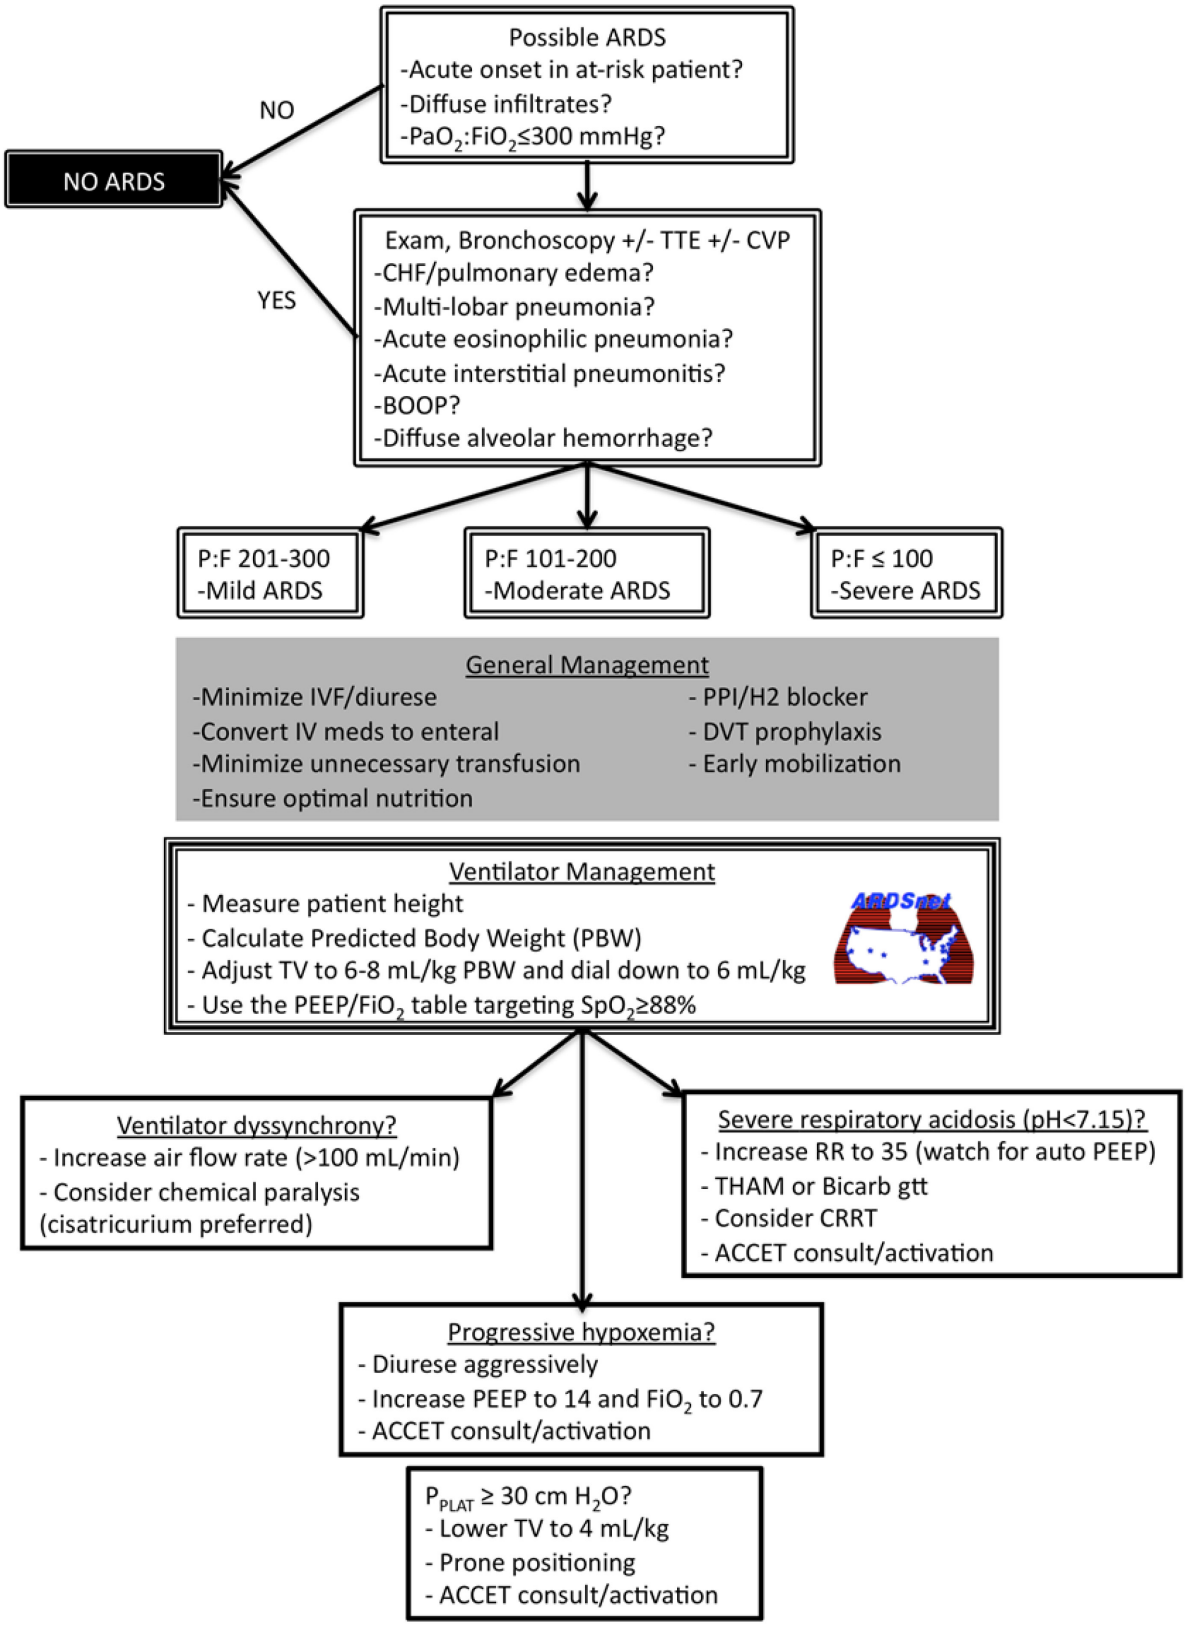
APPENDIX A: DIAGNOSIS AND MANAGEMENT OF ARDS



APPENDIX B: ARDSNET VENTILATOR MANAGEMENT FOR PATIENTS WITH ARDS[23]

NIH NHLBI ARDS Clinical Network
Mechanical Ventilation Protocol Summary

INCLUSION CRITERIA: Acute onset of

1. $PaO_2/FiO_2 \leq 300$ (corrected for altitude)
2. Bilateral (patchy, diffuse, or homogeneous) infiltrates consistent with pulmonary edema
3. No clinical evidence of left atrial hypertension

PART I: VENTILATOR SETUP AND ADJUSTMENT

1. Calculate predicted body weight (PBW)
   Males = 50 + 2.3 [height (inches) - 60]
   Females = 45.5 + 2.3 [height (inches) -60]
2. Select any ventilator mode
3. Set ventilator settings to achieve initial V_T = 8 ml/kg PBW
4. Reduce V_T by 1 ml/kg at intervals ≤ 2 hours until V_T = 6ml/kg PBW.
5. Set initial rate to approximate baseline minute ventilation (not > 35 bpm).
6. Adjust V_T and RR to achieve pH and plateau pressure goals below.

OXYGENATION GOAL: PaO_2 55-80 mmHg or SpO_2 88-95%
Use a minimum PEEP of 5 cm H_2O. Consider use of incremental FiO_2/PEEP combinations such as shown below (not required) to achieve goal.

Lower PEEP/higher FiO2

FiO_2	0.3	0.4	0.4	0.5	0.5	0.6	0.7	0.7
PEEP	5	5	8	8	10	10	10	12

FiO_2	0.7	0.8	0.9	0.9	0.9	1.0
PEEP	14	14	14	16	18	18-24

Higher PEEP/lower FiO2

FiO_2	0.3	0.3	0.3	0.3	0.3	0.4	0.4	0.5
PEEP	5	8	10	12	14	14	16	16

FiO_2	0.5	0.5-0.8	0.8	0.9	1.0	1.0
PEEP	18	20	22	22	22	24

PLATEAU PRESSURE GOAL: ≤ 30 cm H_2O
Check Pplat (0.5 second inspiratory pause), at least q 4h and after each change in PEEP or V_T.
If Pplat > 30 cm H_2O: decrease V_T by 1ml/kg steps (minimum = 4 ml/kg).
If Pplat < 25 cm H_2O and V_T< 6 ml/kg, increase V_T by 1 ml/kg until Pplat > 25 cm H_2O or V_T = 6 ml/kg.
If Pplat < 30 and breath stacking or dys-synchrony occurs: may increase V_T in 1ml/kg increments to 7 or 8 ml/kg if Pplat remains ≤ 30 cm H_2O.

pH GOAL: 7.30-7.45
Acidosis Management: (pH < 7.30)
If pH 7.15-7.30: Increase RR until pH > 7.30 or $PaCO_2$ < 25 (Maximum set RR = 35).
.
If pH < 7.15: Increase RR to 35.
If pH remains < 7.15, V_T may be increased in 1 ml/kg steps until pH > 7.15 (Pplat target of 30 may be exceeded).
May give $NaHCO_3$
Alkalosis Management: (pH > 7.45) Decrease vent rate if possible.

I: E RATIO GOAL: Recommend that duration of inspiration be ≤ duration of expiration.

PART II: WEANING

A. Conduct a SPONTANEOUS BREATHING TRIAL daily when:

1. $FiO_2 \leq 0.40$ and PEEP ≤ 8 OR $FiO_2 \leq 0.50$ and PEEP ≤ 5.
2. PEEP and FiO_2 ≤ values of previous day.
3. Patient has acceptable spontaneous breathing efforts. (May decrease vent rate by 50% for 5 minutes to detect effort.)
4. Systolic BP ≥ 90 mmHg without vasopressor support.
5. No neuromuscular blocking agents or blockade.

B. SPONTANEOUS BREATHING TRIAL (SBT):
If all above criteria are met and subject has been in the study for at least 12 hours, initiate a trial of UP TO 120 minutes of spontaneous breathing with FiO2 ≤ 0.5 and PEEP ≤ 5:

1. Place on T-piece, trach collar, or CPAP ≤ 5 cm H_2O with PS ≤ 5
2. Assess for tolerance as below for up to two hours.
   a. $SpO_2 \geq 90$: and/or $PaO_2 \geq 60$ mmHg
   b. Spontaneous $V_T \geq 4$ ml/kg PBW
   c. RR ≤ 35/min
   d. pH ≥ 7.3
   e. No respiratory distress (distress= 2 or more)
      - HR > 120% of baseline
      - Marked accessory muscle use
      - Abdominal paradox
      - Diaphoresis
      - Marked dyspnea
3. If tolerated for at least 30 minutes, consider extubation.
4. If not tolerated resume pre-weaning settings.

Definition of UNASSISTED BREATHING
(Different from the spontaneous breathing criteria as PS is not allowed)

1. Extubated with face mask, nasal prong oxygen, or room air, OR
2. T-tube breathing, OR
3. Tracheostomy mask breathing, OR
4. CPAP less than or equal to 5 cm H_20 **without pressure support or IMV assistance.**

APPENDIX C: PRONE POSITIONING IN PATIENTS WITH ARDS

PREPARATION:

1. Check for contraindications.
   - Facial or pelvic fractures
   - Anterior torso wounds or burns
   - Spinal instability
   - Increased ICP
2. Confirm ETT placement with recent CXR.
3. Ensure that ETT and all invasive lines/monitors (chest tubes, IVs, central lines) are secured.
4. Consider how patient's head, neck, shoulder girdle will be supported.
5. Stop tube feedings, evacuate stomach, cap/clamp feeding and gastric tubes.
6. Prepare airway suctioning equipment.
7. Prepare all IV tubing, catheters, etc., for prone connections.
   - Assure sufficient tubing length
   - Relocate drainage bags to opposite side of bed
   - Move chest tube drains to between legs
   - Reposition IV tubing to patient's head on opposite side of bed

TURNING

1. Place personnel on both sides and head of bed.
2. Increase FiO_2 to 1.0, and note TV, minute ventilation, peak/plateau pressures.
3. Place new draw sheet, put patient into lateral decubitus position.
4. Remove EKG leads and patches. Suction airway, oropharynx, nares as necessary.
5. Continue to proning, and reposition patient in center of bed.
6. Turn patient's face toward ventilator. Ensure airway is not kinked and has not migrated.
7. Support face/shoulders appropriately; ensure no contact of padding with eyes/orbits.
8. Position patient's arms for comfort. Avoid arm extension that might cause brachial plexopathy.
9. Auscultate chest for mainstem intubation; reassess TV and minute ventilation.
10. Reconnect and adjust all tubing, check functions.
11. Reattach ECG patches and leads to back.
12. Tilt patient in reverse Trendelenburg. Intermittent slight (200) lateral repositioning every two hours, if possible.
13. Document skin assessment on weight-bearing surfaces every shift.

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Airway Management in Prolonged Field Care

This Role 1 prolonged field care (PFC) CPG is intended to be used after Tactical Combat Casualty Care (TCCC) Guidelines, when evacuation to higher level of care is not immediately possible.

PURPOSE

This Role 1, prolonged field care (PFC) clinical practice guideline (CPG) is intended to be used after Tactical Combat Casualty Care (TCCC) Guidelines, when evacuation to higher level of care is not immediately possible. A provider must first and foremost be an expert in TCCC, the Department of Defense standard of care for first responders. The intent of this PFC CPG is to provide evidence and experience-based solutions to those who manage airways in an austere environment. An emphasis is placed on utilizing the tools and adjuncts most familiar to a Role 1 provider. The PFC capability of airway is addressed to reflect the reality of managing an airway in a Role 1 resource-constrained environment. A separate Joint Trauma System CPG will address mechanical ventilation. This PFC CPG also introduces an acronym to assist providers and their teams in preparing for advanced procedures, to include airway management.

BACKGROUND

Airway compromise is the second leading cause of potentially survivable death on the battlefield after hemorrhage.[1] Complete airway occlusion can cause death from suffocation within minutes. Austere environments present significant challenges with airway management. Limited provider experience and skill, equipment, resources, and medications shape the best management techniques. Considerations include: limited availability of supplemental oxygen; medications for induction/rapid sequence intubation, paralysis, and post-intubation management; and limitations in available equipment. Another reality currently is limitations in sustainment training options, especially for advanced airway techniques. Due to these challenges, some common recommendations that may be considered "rescue" techniques in standard hospital airway management may be recommended earlier or in a non-standard fashion to establish and control an airway in a PFC environment. Patients who require advanced airway placement tend to undergo more interventions, be more critically injured, and ultimately have a higher proportion of deaths. The ability to rapidly and consistently manage an airway when indicated or spend time on other resuscitative needs when airway management is not indicated, may contribute to improved outcomes.[2,3]

INDICATIONS FOR AIRWAY MANAGEMENT

DISRUPTED FACE OR NECK ANATOMY

If managing an isolated injury that disrupts face or neck anatomy, healthy adults may only need a mechanical airway placed and may not require assisted ventilation if they are not heavily sedated. Examples of conditions requiring early airway management include:

- Massive facial trauma
- Burns to the face or inhalation injury with hoarseness or stridor
- Massive neck trauma
- Expanding neck mass/hematoma
- Acute pharyngeal infection (Retropharyngeal abscess, peritonsillar abscess, epiglottitis)
- Foreign body aspiration
- Anaphylaxis (airway swelling)

INSUFFICIENT OXYGENATION OR VENTILATION

These indications may be apparent on initial evaluation or may emerge during the course of patient management. If the need to establish an airway develops more gradually, additional elective airway techniques can be employed. Interventions such as prolonged manual bag or mechanical ventilation require an airway intervention to ensure best overall management. Examples include:

- Chest wall and pulmonary trauma (blunt or penetrating) such as flail segments, pulmonary contusions (from blast, blunt or crush mechanism)
- Burns with greater than 40% body surface area
- Traumatic brain injury with decreased level of consciousness (GCS ≤ 8)
- Traumatic brain injury with suspected herniation requiring hyperventilation (target $ETCO_2$ between 30 and 35)
- Procedural sedation or surgical procedure
- Respiratory failure from disease, infection, or injury:
  - Chemical or toxic inhalation injuries
  - Acute Respiratory Distress Syndrome (ARDS) from infection, massive resuscitation, drug-induced or other causes
  - Primary lung infection (pneumonia)
  - Massive pulmonary embolism
  - TRALI (transfusion related acute lung injury) or TACO (transfusion associated circulatory overload) due to massive transfusion

Table 1. TCCC Airway Management Adjuncts (Consider basic adjuncts first)

DEVICE/ TECHNIQUES	PROS	CONS	PHARM REQS TO MAINTAIN (0/+/++)	SKILL LEVEL (NM: NON-MEDIC; M: MEDIC)
Head-Tilt/ Chin-Lift	Easy	Requires hands-on continuously	0	NM
Recovery Position	Easy; tactically feasible (TCCC/MASCAL)	May limit patient assessment or ongoing management	0	NM
Sit Up/ Lean Forward	Easy and practical (position of comfort)	May indicate impending airway loss	0	NM
Nasopharyngeal Airway (NPA)	Easy	Risk of nose bleeds with placement	0	NM
Oropharyngeal Airway (OPA)	Easy	Not tolerated in conscious patient	+	NM
Supraglottic Airway (SGA)	Easy	Not tolerated in conscious patient	++	M

DEVICE/ TECHNIQUES	PROS	CONS	PHARM REQS TO MAINTAIN (0/+/++)	SKILL LEVEL (NM: NON-MEDIC; M: MEDIC)
Oral Endotracheal Tube (ETT) Airway	Familiar to trained providers; Definitive; No surgical incision needed	Skill sustainment challenging, requires neuromuscular blockade (rapid-sequence intubation) for best success, may require suction to visualize vocal cords, requires sedation (potential limitation in PFC)	++	M+
Cricothyrotomy (Cric)	Definitive; Better tolerated than Oropharyngeal (OP), SGA or ETT. May require less sedation to sustain once in place	Invasive procedure, high failure rate in some studies.[4,5]	+	M

For Pharm Reqs: Maintain: 0 = no additional medications; + = some or intermittent dosing medications required; ++ = continuous or multiple medications required

MACHINE, SUCTION, MONITOR, AIRWAY, INTRAVENOUS ACCESS, DRUGS

Checklists are commonly used in medical practice. In preparation for an advanced procedure (including securing an airway) using an acronym or other checklist approach will prove invaluable. One such acronym, originally developed as a simple pre-operative anesthesia checklist, is presented.
The MSMAID acronym (Machine, Suction, Monitor, Airway, Intravenous access, Drugs) organizes an approach to preparation for airway management and may also prove useful in preparation for other procedures.

The patient's condition dictates the available time for a provider to consider all items on this checklist. A rapidly deteriorating patient with airway disruption or compromise will need the airway procedure first and follow-on considerations later. If a patient can be more appropriately classified as semi-urgent (e.g., worsening respiratory status due to an underlying pulmonary cause) the provider will have more time to consider the algorithm and prepare. Logistic considerations, and sometimes considerable time constraints, will affect preparation for advanced procedures. Recommendations follow the "minimum, better, best" format.

MACHINE

(Equipment required post-intubation)

- **Minimum**: Bag-Valve-Mask (BVM) with positive end-expiratory pressure (PEEP) valve
- **Better**: Automated portable ventilator (preferably with PEEP); oxygen concentrator
- **Best**: Full-feature portable ventilator (e.g. several ventilatory modes, PEEP); supplemental oxygen if available

Managing ventilators or advanced equipment unfamiliar to a provider presents challenges. Initiate telemedicine consultation for best guidance.

PEEP is important for prolonged ventilation. PEEP is the pressure in the airway at the end of the expiratory phase which prevents the alveoli of the lung from completely collapsing. In a spontaneously breathing person, this pressure is maintained by closing the glottis, clearing the throat, coughing, sighing, etc. With an invasive airway, the glottis is bypassed with the tube and "natural" PEEP is lost. PEEP should therefore be introduced into the ventilated patient using a PEEP valve on the BVM or using the PEEP setting on a ventilator. When using BVM or ventilator, provide PEEP (recommended initial setting is 5cm H2O).[6]

SUCTION

- **Minimum**: Improvised suction (i.e. syringe + nasopharyngeal airway [NPA]) and patient positioning if not contraindicated
- **Better**: Manual suction bulb with adapter
- **Best**: Powered commercial suction with oral tip and in-line endotracheal tube suction adapter

Suction should be available when establishing and maintaining an airway to remove excessive secretions or blood. It is particularly important to utilize suction to facilitate view of the vocal cords during endotracheal intubation. In addition, suction should be available for routine patient care and maintenance requirement for any intubated patients. Suction should be utilized as needed to remove secretions, mucous or blood from the airway device or oropharynx. In the event of high airway pressures, suction may be used to remove mucus/mucus plugs or to clear obstructions. In the case of thick secretions, a saline flush of 1-2 mL followed by in-line suctioning of the endotracheal tube may be useful.
Note: *During in-line suctioning of tubes, the suction should only be applied when withdrawing the catheter and not upon initial insertion.*

MONITOR

(Monitoring and telemedicine support)

- **Minimum**: Pulse oximeter (SpO2), assistant to monitor respirations and record manual vital signs. Trending vital signs documentation. PFC flow sheet is recommended. Refer to *PFC Documentation CPG*.[7] Voice or data connections to perform telemedicine communication
- **Better**: Portable Capnometry ($ETCO_2$)/capnography in addition to SpO2. Transmit photographs from smartphones or personal devices to augment telemedicine communications.
- **Best**: Automatic vital signs monitor with SpO2, $ETCO_2$/waveform capnography, +/- electrocardiogram (EKG); Synchronous (real-time continuous) telemedicine using video or remote patient monitoring systems

Monitoring is the active process of assessing the patient throughout a procedure. It involves the gathering, documenting and interpretation of vital signs and other data, and the continuous assessment of their clinical status. Telemedicine can be an important adjunct and critical capability to employ when monitoring a patient undergoing complex procedures.

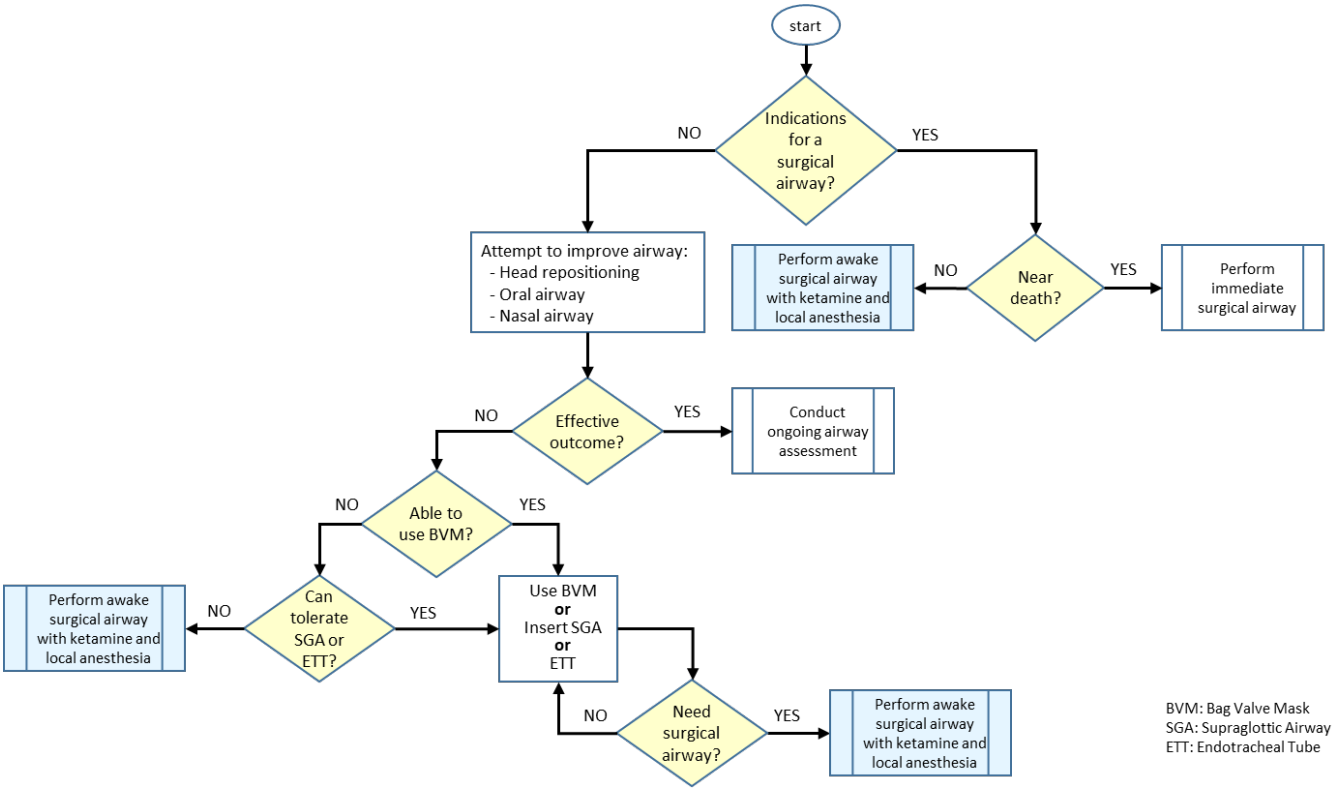
AIRWAY

- **Minimum**: Medic is prepared for a ketamine cricothyroidotomy.
- **Better**: Add ability to provide continuous sedation.
- **Best**: Add a responsible rapid-sequence intubation capability (to include chemical paralysis) with airway maintenance (to include suction) and continuous sedation.

Per the PFC Capabilities Position Paper, a definitive airway requires control of the patient's airway with an inflated cuff in the trachea. In addition, sedation is needed to keep the patient comfortable and sustain the airway.[8]

A proposed algorithm was developed by Mabry RL et al for an awake surgical airway (Figure 1).[9] This algorithm incorporates the skills recommended for Tactical Combat Casualty Care and presents the decision process deemed adequate (minimum standard) for definitive airway control in PFC. The airway algorithm is presented in its published form and surgical airway is synonymous with cricothyrotomy. As noted above, the indications for surgical airway include disrupted face or neck anatomy, as well as a need for prolonged positive pressure ventilation in a resource constrained PFC environment. Consider temporizing, if possible, with basic airway maneuvers or other airway adjuncts (e.g.; NPA, SGA). Please see Table 1.

Figure 1. An Awake Patient Surgical Airway Algorithm



Source: Mabry RL, Kharod CU, Bennett BL. Awake cricothyrotomy: a novel approach to the surgical airway in the tactical setting. Wilderness Environ Med. 2017;28(2S):S61-8. Adapted with permission from the Wilderness Medical Society. ©2017 Wilderness Medical Society.

Positioning of the patient to help clear airway obstruction should be considered first, when possible. The simple option of placing the patient in a sitting position, placing the patient in the lateral "recovery" position, or head tilt-chin lift/jaw thrust maneuver may be enough to ensure adequate respirations. Simple adjuncts such as a nasal or oropharyngeal airway (in an unconscious patient) may be utilized in addition to proper positioning to help ensure a clear airway.

For those patients requiring active airway assistance, the first step should be inserting an NPA to open the airway. BVM ventilation is the next step in the algorithm and though it appears to be relatively simple, the procedure requires preparation, training and skill to perform correctly. A spontaneously breathing patient may prove challenging, but properly delivered, synchronous breaths may be the only requirement to assist a patient's respirations. Care should be taken to ensure proper volume and rate of bag-delivered breath. One hand should provide moderate pressure to the bag for no more than 50% of the volume of an adult bag or just enough to see the chest begin to rise at a rate of 12-16 breaths per minute (one breath every 4-5 seconds) initially. It is important to avoid hyperventilation through large or rapid breaths, particularly with traumatic brain injury (TBI) casualties, therefore $ETCO_2$ monitoring is indicated for all patients requiring assisted ventilation and all patients with altered mental status (including both TBI casualties and sedated patients). BVM is an important airway management skill (see Appendix C: Bag-Valve-Mask Technique for a detailed description). It is highly recommended that all PFC training on airway skills cover BVM skills and techniques.

OP and SGA insertion can present a considerable noxious stimulus and may not be tolerated by conscious or even some semiconscious patients. Additionally, the dyssynchronous use of BVM ventilation may lead to poor patient cooperation, abnormal tidal volumes, gastric insufflation (and resultant regurgitation/aspiration), or other complications.

The decision to perform a cricothyroidotomy is one that is sometimes difficult. When possible, in urgent but not emergency situations, a telemedicine call should be considered to help with medical decision making.

An important adjunct to passing an endotracheal tube, either via the cricothyroid membrane or the oropharynx, is the use of a gum elastic bougie (sometimes also referred to as an Eschmann Stylet or, simply bougie). This device is simple, rugged and should be used to guide tube placement. The bougie is placed in the trachea before the endotracheal tube and may be used first to confirm proper positioning by either tactile discrimination (feeling the tube bump against the tracheal rings on introduction), or by encountering a hard stop when abutted against the carina. An endotracheal tube is then introduced over the bougie into the trachea. Lastly, the bougie is removed. A bougie may also be used to change tubes in the case of a tube malfunction. This may be accomplished by placing a bougie in a tube that is currently positioned, remove the tube over the bougie (ensuring the bougie remains in the proper position within the airway lumen), and replacing a new tube over that bougie. Remove the bougie, leaving the new tube in place. Confirmation procedures discussed below must be repeated once the new tube is in place.

Consistent with TCCC guidelines, the routine use of orotracheal intubation is not recommended as the minimum standard in PFC. This procedure requires considerable skill and sustainment;[10] and requires appropriate sedation for both rapid sequence intubation and post-intubation management. If a provider is appropriately trained, current and practiced in the procedure, and has the required support equipment and medications, then orotracheal intubation may be considered. Although preferred when

possible, training in orotracheal intubation is not required to obtain a definitive airway in the PFC operational setting. Consider basic measures first before proceeding to either type of invasive airway. Additional details on orotracheal intubation are included in the *JTS Airway CPG*.

Airway management in the tactical setting requires a different conceptual approach than airway management in the hospital, or even the civilian prehospital environment. Differences in epidemiology, injury patterns, equipment and environment must be considered if airway management is to be optimized. First, most military casualties requiring a prehospital airway have trauma to the head, face or neck. Surgical airway is often the final common pathway due to bleeding or distorted anatomy. In comparison, most airways in the civilian prehospital environment are placed in elderly people for cardiac arrest. When reliable suction and oxygen delivery are not available, or personnel are not experienced in rapid sequence intubation using neuromuscular blockade, a definitive airway will often mean a surgical airway.

Proper Tube Placement

- **Minimum**: Visualization of the tube passing through the vocal cords (in the case of endotracheal intubation); auscultation of epigastric region (should be silent) and bilateral lung sounds (should be present). Colorimetric capnography + endotracheal detection device (EDD). Easy bilateral rise and fall of the chest + misting of the tube + no signs of gastric insufflation. (Reassess frequently and have another medic double check if unsure.)
- **Better**: Minimum plus portable capnometer. Ultrasound if trained/available to guide and/or verify placement
- **Best**: Continuous $ETCO_2$/waveform capnography

Verification of correct tube placement must be performed every time as incorrect tube placement may be fatal. The REACH study[5] showed that right mainstem and hypopharynx placement are the most common locations of incorrect placement of ETT. Esophageal intubation is also common. Subcutaneous placement of cricothyroidotomy tube may occur. Use capnography to verify correct tube placement as tube misplacement can be fatal. Auscultate, if possible, to verify bilateral breath sounds. If ultrasound is available, this can be used to further verify placement in the correct position.[11]

IV/IO ACCESS

- **Minimum**: If (IV) / intraosseous (IO) attempts fail or when unavailable: medication may be given intramuscularly or intranasally for immediate sedation to facilitate surgical cricothyroidotomy. Continue attempts at IV/IO access after airway has been controlled
- **Better**: 1-2 patent IV/IO
- **Best**: 2-3x patent intravenous IV/IO with additional IO device on standby

Though an important consideration to administer medications and fluids, do not delay an emergent airway to obtain IV/IO access in the instance you are the sole provider.

Ultrasound may be used to help identify small or deep veins. Ultrasound guided IV access may be attempted if trained. Other sites to consider for superficial IV attempts include the external jugular and saphenous veins. If appropriately trained, consider central venous access or venous cutdown.

DRUGS

Airway Placement

- **Minimum**: Local anesthetic for cricothyroidotomy (superficial skin anesthesia plus 1-2 mL injected through the cricothyroid membrane); or placement without medications in unconscious patient. **Note: most sedating agents can be given IM if IV/IO has not been established
- **Better**: Any IV/ IO sedating agent (opioid, benzodiazepine: reference the *Analgesia and Sedation Management for PFC CPG* for procedural doses of such agents).[12]
- **Best**: Procedural dose ketamine (1-2 mg/kg IV push) for ETT or cricothyroidotomy placement + local anesthetic (lidocaine) for cricothyroidotomy placement

Prolonged Sedation

(post-airway placement)

- **Minimum** (without IV access): Ketamine (sedation dose), 3-4mg/kg IM
- **Better**: IV/IO pushes of ketamine, opioid, and/or midazolam (alone or in combination as per the individual's scope of practice, experience and availability of medications)
- **Best**: Ketamine IV/IO Drip. Hydromorphone or alternate opioid IV/IO push for breakthrough pain and midazolam IV/IO push as needed for sedation

(Reference Analgesia and Sedation Management in PFC CPG for details and drug doses).[12]

Be cautious with sedation, advanced airway placement and positive pressure ventilation in patients who are hypotensive or under-resuscitated. Blood pressure can fall rapidly during airway management due to a variety of mechanisms.

In all cases, monitor BP closely (every 1-2 minutes during the procedure, every 3-5 minutes for 15 minutes post-procedure). A BP drop may be brief (if due to vagal effects of epiglottis stimulation during ETT placement) or sustained (due to positive pressure ventilation, increased intrathoracic pressure and decreased venous return to the heart). Loss of sympathetic drive secondary to pain and sedation medications, and/or continued hypovolemia can also result in hypotension. Continue resuscitation with blood products (trauma patients) or crystalloid (non-trauma patients) if a hypotensive patient requires immediate airway interventions. Be prepared to support blood pressure with vasopressors (e.g. epinephrine bolus or drip) if trained or under direct telemedicine guidance.

Neuromuscular blockade (succinylcholine, rocuronium, vecuronium, etc.) is NOT recommended for use by the average practitioner of PFC. Though these are standard medications to use in rapid sequence intubation and ventilator management, their potential lethality in inexperienced hands does not justify routine recommended use. If trained and/or under direct supervision of telemedicine support, the use of neuromuscular blockade may be considered, subject to local medical direction and protocols.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

1. All patients who received ETT/cricothyroidotomy/supraglottic airway/NPA
2. All patients with compromised airway (initial GCS < 8 or abbreviated injury scale (AIS) head and neck ≥ 3, or AIS face ≥ 3).

INTENT (EXPECTED OUTCOMES)

1. All injured patients who present with obtundation (GCS<8), apnea, respiratory distress or insufficiency, airway obstruction, or impending airway loss will have a secure and definitive airway established expeditiously upon arrival to a Role 2 or Role 3 if not done prehospital.
2. SpO2 is maintained between≥ 90% and 96%. SpO2 >96% is not necessary.[13]
3. Patients with a definitive airway (endotracheal tube, cricothyroidotomy, tracheostomy) have $ETCO_2$ monitoring to confirm airway placement.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who had a secure and definitive airway (endotracheal tube, cricothyroidotomy, tracheostomy) established or verified, or documentation of appropriate intervention.
2. Number and percentage of patients in the population of interest with SpO2 < 90%<80%, <70%, <60%.
3. Number and percentage of patients who had definitive airway (endotracheal tube, cricothyroidotomy, tracheostomy) with $ETCO_2$ documented at the same role of care where the procedure is done.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

APPENDIX A: AIRWAY EQUIPMENT

AIRWAY EQUIPMENT

- **Minimum** (Ruck/Aid Bag): Nasopharyngeal airway, Cricothyrotomy kit; BVM with PEEP valve
- **Better**: Minimum PLUS supraglottic airway, gum elastic bougie to facilitate intubation, nasogastric/orogastric tube
- **Best**: Better PLUS endotracheal tubes or video laryngoscopy equipment is preferred (direct laryngoscope only if video equipment not available).[1]

WAVEFORM CAPNOGRAPHY

- **Minimum**: Colorimetric $ETCO_2$ detector
- **Better**: Portable capnometer
- **Best**: Waveform capnography on patient monitor

See Appendix G for Capnography Interpretation

HEAT-MOISTURE EXCHANGER

Heat-Moisture Exchangers (HME) are small, relatively inexpensive, in-line ETT adjuncts that contain hygroscopic salts that utilize differences in vapor pressure, expired moisture content, and the patient's temperature to increase the humidity of inspired air. Increased moisture on inspiration helps maintain alveolar moisture. Capnography should not be positioned in-line following HME as these moisture devices can increase breathing resistance and work of respiration, as well as increase breathing apparatus dead space (especially in pediatric patients). This may lead to potential worsening hypercapnia and respiratory acidosis. Recommended order: endotracheal tube-capnograph-HME device (proximal to distal).

NASOGASTRIC/OROGASTRIC TUBE:

Placement of a nasogastric (NG) or orogastric (OG) tube should be considered following intubation of a patient in order to decompress gastric contents, prevent aspiration and gastric distention.

- If only supraglottic airway access is available, consider using a supraglottic device that incorporates an orogastric tube port.
- Always measure the distance from nose to stomach and note the distance prior to insertion, then verify epigastric sounds. Verify placement with second practitioner if sounds are questionable or difficult to auscultate.
- Do not feed, aggressively hydrate or give oral medications through an OGT or NGT without telemedicine guidance. Always reassess tube position prior to putting anything into stomach to ensure proper gastric placement. Feeding should not be considered until 72 hours after injury in the PFC environment. If volume instilled is too large or rate is too fast, there is increased risk for vomiting. If feeding or hydration is begun through an OGT or NGT, they must be accurate, measured, and monitored. Safe airway management takes precedence over nutrition.

1. Prekker ME, Driver BE, Trent SA, et al. DEVICE Investigators and the Pragmatic Critical Care Research Group. Video versus direct laryngoscopy for tracheal intubation of critically ill adults. N Engl J Med. 2023 Aug 3;389(5):418-429

SUGGESTED PACKING LIST

	EQUIPMENT	NOTES
Minimum	Nasopharyngeal airway (NPA)	
	Oropharyngeal airway (OPA)	
	Cricothyroidotomy kit: a standardized kit should include at a minimum a #10 scalpel, a tracheal hook (or small, curved hemostat), an airway tube, a 10mL syringe, and a securing strap. The airway tube may be a prefabricated cricothyroidotomy tube such as that included in the Cric-Key (Control Cric), a Shiley tracheostomy tube, or a 6.0-sized endotracheal tube.	
	Bag valve mask (BVM)	
	PEEP valve: either separate device, or affixed to the BVM device	
	Capnography/capnometry device	
	Bougie	
Better	Additional endotracheal tubes	
	Portable suction device	
Best	Supraglottic airway: options include LMA (Size 4 if only one; size 5 for >90kg patient) or King-LT.	
	Waveform capnography	
	Commercial power suction device	
	Automatic (electronic) patient monitor	
	Direct laryngoscope: Macintosh blade size 3 or 4 for adults; Miller 1 or 2 for infants and small children as needed. Video laryngoscope preferred (direct laryngoscope only if video not available). [1]	For those trained in endotracheal tube placement and opt to include equipment in their aid bag
	Endotracheal tubes: for cricothyroidotomies (6.0 mm tubes). Personnel trained in endotracheal intubation should also carry a 7.5 or 8.0mm tube for primary intubation. A 7.0 mm tube should be carried as a secondary ET tube in case of difficult intubation. (If pediatric trauma is common, consider adding smaller sizes, but these should be limited to the most common ages expected to encounter, and calculated on the classic rule of tube size = 4 + (age/4). Examples of what to carry include 4.0 mm uncuffed for infants, and 6.0 cuffed for older children).	For those trained in endotracheal tube placement and opt to include equipment in their aid bag
	Video laryngoscope: hand-held devices should utilize a blade with an angle that allows for direct laryngoscopy function should the video screen/battery fail during intubation.	For those trained in endotracheal tube placement and opt to include equipment in their aid bag
	Mechanical ventilator	
	Pediatric-sized equipment	
	Other equipment listed above but not carried due to cube/weight restrictions	

APPENDIX B: AIRWAY MANAGEMENT NURSING/CONTINUED CARE

Long-Term Airway Management, Nursing and Prolonged Field Care

Below is the recommended Prolonged Field Care Nursing Flowsheet to use as a guide.*

Patient ID:			Time	1hr	2hr	3hr	4hr	5hr	6hr	7hr	8hr	9hr	10hr	11hr	12hr	13hr	14hr	15hr	16hr	17hr	18hr	19hr	20hr	21hr	22hr	23hr	24hr
	Action (suggested interval)	Interval																									
Vitals	Check BP/HR/RR/T/SPO2/$ETCO_2$ (Q1H)																										
	Check Peripheral Pulses (Q1H)																										
	Check Skin Temp and Color (Q1H)																										
	Check Lactate (Q4H)																										
	Check Blood Glucose (Q8H)

	Give Antiemetic Rx (per Rx)																										
	Auscultate Abdomen (Q2H)																										
	Palpate Abdomen (Q2H)																										
	Give Food/Nutrition (Q8H)																										
Extra Stuff	Check O2 Supply																										
	Check/change batteries																										
	Compression Socks/Stockings																										

AIRWAY-SPECIFIC PFC NURSING GUIDELINES/ASSESSMENT/TASKS

- Oral Suction (or in-line/tube suctioning, if placed) as indicated during routine patient assessments
- Nose and mouth moistened Q4H
- Lip Balm applied Q1H
- Teeth brushed Q12H - Prevents pneumonia and other infections.
- Auscultate lungs Q1H. If available, get a second medic to double check and verify if sounds are questionable or cannot otherwise auscultate. Extra diligence should be given to check for diminished breath sounds for suspected pneumothorax, as well as for pulmonary edema, especially if giving aggressive fluids in the case of a massive resuscitation, or replacement fluids. Consider ultrasound evaluation if available.

Naso/Orogastric Tube (NGT/OGT) and Abdominal Care

(as applicable)

- Consider placing an NG/OG tube for prolonged care of intubated/cricothyrotomy patient or those with an SGA in place (if a compatible port is available on the SGA).
- Abdominal palpation AND auscultation Q2H.
- Nutrition ONLY under telemedicine guidance (optional and not indicated in first 72 hours).

**Loos PE, Glassman E, Doerr D, et al. Documentation in prolonged field care. J Spec Oper Med. 2018; 18(1): 126-32.*

APPENDIX C: BAG-VALVE-MASK TECHNIQUE

Proper technique is essential to perform successful bag-valve-mask (BVM) airway management. Patients should be in the supine position, neck in a neutral position and the occiput slightly elevated (on a folded blanket, sheet, small pillow, etc.) to achieve a "sniffing position," with the opening of the ears at the same level as the sternal notch. Masks should be of the proper size and should be fitted to the face to obtain a seal. This is best achieved by first placing the tapered portion of the opening of the mask over the bridge of the nose, then covering the patient's mouth. If using the one-person method, the non-dominant had should use the "C & E" method with the thumb and index finger forming a C to cover the mask, and the middle, ring and small fingers forming an E on the bone of the mandible effectively lifting the jaw into the mask (rather than pressing the mask onto the face).

The other hand should gently squeeze the bag delivering a breath at a rate of one squeeze every 5-6 seconds. There should not be a leak around the mask, and you should be able to observe the rise and fall of the patient's chest. An $ETCO_2$ monitor may be placed in-line with the bag and mask. PEEP should be used with the BVM and initially set to 5mmHg. Every attempt should be made to maintain a seal to ensure continued PEEP. If the patient is breathing spontaneously, careful observation and delivery of an assisted synchronous breath should be a priority.

Some additional considerations are below:

1. If unable to perform adequate single hand C & E clamp, use two handed technique with a second person to bag.
2. Don't press mask down onto face when performing C & E clamp, visualize you are lifting face into mask.
3. Be aware fingertips on "E-clamp" should be positioned on the bones of the mandible and not on soft tissue, which could possibly occlude the airway.
4. Use "BOOTS" to predict difficult face-mask seals: Bearded, Obese, Old, Toothless, Snoring. In addition, maxillofacial trauma and edema from burns may prevent effective ventilation by BVM.
5. NPA should be used to assist with face mask ventilations (unless obvious contraindications such as mid-face trauma). OPA are also effective in obtunded patients or those who have received chemical sedation or neuromuscular blockade.
6. For bearded patients, lubrication of mask may assist seal. Tegaderm occlusive dressings over beard may also help if available. (If Tegaderm is used in sedated patient, consider pulling off before medication wears off, to lessen pain).
7. Consider mask straps to make face-mask seal more "hands free", especially if a non-medic is assisting you with BVM.

APPENDIX D: SUPRAGLOTTIC AIRWAY PLACEMENT

SUPRAGLOTTIC AIRWAY (SGA) PLACEMENT CHECKLIST

- ☐ Open airway manually, measure and insert simple airway adjunct (NPA -or- OPA).
- ☐ Ventilate patient with bag-valve-mask (BVM) (attach supplemental oxygen, if available).
- ☐ If ventilations insufficient, or the patient is clearly unconscious and not breathing adequately, prepare for supraglottic airway insertion. Inspect SGA to ensure appropriate size. Lubricate airway to facilitate passage. Cricothyroidotomy kit should be prepared for use if SGA fails.
- ☐ Follow MSMAID and for induction, use ketamine (1-2 mg/kg IV/IO or 3-4mg/kg IM) if time permits and the recommended medications are available.

INSERTING THE AIRWAY:

- ☐ Properly position head in a neutral or "sniffing" position (neck extended, as on a pillow or small blanket while lying flat) and open airway.
- ☐ Remove oropharyngeal airway (OPA) if previously placed.
- ☐ Insert device to proper depth (may adjust later if need for improved ventilation).
- ☐ Inflate cuff, if applicable; inflate as per device-specific volume instructions and immediately remove syringe.
- ☐ Confirm placement with ventilation and auscultation over epigastrium, then bilaterally over chest, left lung then right lung. Get a second practitioner to double check and verify in sounds are questionable or cannot otherwise auscultate.
- ☐ Verify proper SGA placement by secondary confirmation such as capnography/capnometry or colorimetric device.
- ☐ Place orogastric tube and decompress stomach if available, and compatible with SGA device (has a port specifically for OGT placement).

SGA Size Chart

Estimated patient size	LMA	King LT*
Neonates/Infants (up to 5kg)	1	0
Infants 5-10 kg	1.5	1
Infants/Children 10-20kg	2	2
Children 20-30kg	2.5	2.5
Children 30-50kg	3	3*
Adults 50-70kg	4	4*
Adults 70-100kg	5	5*
Adults over 100kg	6	

APPENDIX E: CRICOTHYROIDOTOMY PROCEDURE CHECKLIST

PREPARE PATIENT

1. Pre-oxygenate patient if possible.
2. Inspect/assemble/test equipment for cricothyroidotomy.
3. Prepare site with alcohol and betadine -or- Chlorhexadine (Chlora-prep).
4. Follow MSMAID and for induction, use ketamine (1mg/kg IV/IO or 3-4mg/kg IM) if time permits and the medication is available.

For awake cricothyrotomy: Explain procedure to patient; *Use local anesthesia: lidocaine (1% or 2%), bupivacaine (0.25%, 0.5% or 1%); local through planned incision area AND approx. 1-2mL through cricothyroid membrane

PERFORM PROCEDURE

1. Stabilize thyroid cartilage and keep overlying skin taught. Maintain control with hand until the membrane incision is secured (step 8 below).
2. Locate cricothyroid membrane (Palpate for hyoid and tracheal rings. If unsure or difficult landmarks, then measure three finger widths above sternal notch for adults).
3. Make vertical incision through the skin over cricothyroid membrane.
4. Make horizontal incision through cricothyroid membrane, then immediately:
5. Open and maintain membrane incision with tracheal hook (or curved hemostat, bougie or blunt end of scalpel).
6. Insert endotracheal/tracheostomy tube into opening and direct tube caudad into trachea until the balloon is just inside the airway.
7. Inflate cuff and detach syringe (palpate bulb to ensure it's not under-inflated or over-inflated).
8. Maintain control of tube at all times to prevent dislodgement.
9. Attach waveform capnography, or capnometry, or colorimetric device to confirm proper placement of tube.
10. Being careful not to dislodge the tube, attach BVM with PEEP and further check placement (epigastric and bilateral chest) and adequacy of bilateral insufflation of lungs.
11. Remove BVM (if sufficient respiratory effort), assess respirations for adequacy (rate, rhythm, and quality), assist ventilations if needed.
12. Secure with sutures and tie with girth hitch passed around the neck if time permits. As a stopgap, may use chest seal or secure around the neck with tie, ensuring inflation bulb does not get caught.
13. Consider placing NG/OG tube if available.

APPENDIX F: POST CRICOTHYROTOMY/ENDOTRACHEAL INTUBATION CHECKLIST

POST CRICOTHYROTOMY/ENDOTRACHEAL INTUBATION CHECKLIST

- ☐ Double check placement with waveform capnography or capnometry, placed directly on ET tube adapter.
- ☐ Check proper tube depth (not main stem) by auscultating bilateral lung sounds
- ☐ Check that tube is secured (suture to skin + tie with girth hitch around neck, should be able to fit 2 fingers under the tube tie)
- ☐ Bag-valve-mask (BVM) with positive end-expiratory pressure (PEEP) valve @ 5 of PEEP at proper volume (one hand moderate squeeze) and proper rate (one squeeze every 5-6 seconds)
- ☐ Provide adequate analgesia and sedation (follow analgesia and sedation CPG)
- ☐ Calculate remaining medication and establish analgesia and sedation plan. A patient with a cricothyroidotomy may not require heavy continuous sedation.
- ☐ Raise the head and torso to 30 - 45°
- ☐ Filter and humidify the air with a heat moisture exchanger. Place HME in-line distal to $EtCO_2$ device.
- ☐ As needed, place in-line suction for the tube, and suction the mouth for any excess secretions
- ☐ Check cuff pressure (palpate bulb – should be moderately firm but still compressible)
- ☐ Place orogastric tube, if available.
- ☐ Put a BVM +PEEP valve at the bedside if using a mechanical ventilator.
- ☐ Decontaminate the mouth with chlorhexidine swab or toothbrush without paste as per the nursing care plan.

APPENDIX G: WAVEFORM CAPNOGRAPHY & PULSE OXIMETRY INTERPRETATION

WAVEFORM CAPNOGRAPHY (END TIDAL CO2 ($ETCO_2$)) AND PULSE OXIMETRY (SPO2) INTERPRETATION

Detection of $ETCO^2$ is the most reliable way to continuously monitor ventilation and therefore confirm placement of an advanced airway (the only exception is during CPR when $ETCO_2$ may be undetectable). Waveform capnography is the preferred method to detect $ETCO_2$, and with the development of small, portable devices, is the recommended technique even in austere field environments. Inexpensive colorimetric CO_2 detectors are available, however the color change method may be very difficult to visualize with poor lighting or night vision devices. Waveform capnography measures the end-tidal carbon dioxide that passes through the device as the patient exhales in real time since it is placed directly in-line with the endotracheal tube. $ETCO_2$ may also be attached to a face mask to verify normal and spontaneous breaths if an advanced airway has not been placed. With most portable, field capnographs, a number in mmHg will be appear on the display, which indicates the value of the CO_2 in the exhaled breath and can be an immediate confirmation of correct tube placement. If the airway was placed correctly, and the patient is ventilating normally, the capnograph should read between 35-45 mmHg. Some other examples include:

- $ETCO_2$ = 0: the tube is not transmitting any CO_2: disconnected, tube placed in wrong position or has become dislodged. This may also occur if the patient is dead and there is no gas exchange.
- $ETCO_2$ <35: Hyperventilation. The most common cause is over-bagging the patient, but may also indicate pain or anxiety. The only indication for "induced" hyperventilation is severe traumatic brain injury with signs of acute herniation, GOAL = 30-35 (no less than 30)
- $ETCO_2$ >45: Retaining CO_2, ineffective ventilation may indicate oversedation, primary lung problem, brain injury, worsening obstructive disease (asthma). If the trend is rising, this is an indicator of need for active ventilation assistance (BVM or mechanical ventilator)

During CPR (as an indicator of effectiveness of chest compressions and return of circulation):

- $ETCO_2$ < 10: there is no return of CO_2 to the lungs (no effective circulation). If CPR is initiated, it is ineffective
- $ETCO_2$ = 10-20: EFFECTIVE CPR
- $ETCO_2$ = 40 OR GREATER: You may see an abnormally high CO_2 reading immediately after return of spontaneous circulation (ROSC), for instance after a successful defibrillation or return of effective cardiac activity.

Monitor that can provide waveform capnography can provide much more insight into a patient's ventilation and oxygenation status. A quick reference to the most common waveforms is helpful to understanding the status of a patient.

Pulse oximetry is also of use in monitoring the oxygenation status of a patient. It can be an indirect measure of oxygen delivery to the tissues, and overall pulmonary function. Pulse oximetry monitors oxygenation by measuring absorbance differences between oxyhemoglobin and deoxyhemoglobin through the use of an infrared light. Pulse oximetry, however, has some important key limitations. A pulse oximetry reading indirectly reflects the patient's central (pulmonary) oxygenation status by measuring the peripheral oxygenation. This means that any intervention that addresses oxygenation in the lungs may not be detected by the pulse oximeter until 30-90 seconds after the intervention.

Additionally, if the patient is suffering from carbon monoxide or some other forms of poisoning, the pulse oximetry may read inaccurately. Also, a strong peripheral pulse and warm extremity are required to perfuse the capillary beds of the extremities and allow the pulse oximeter to obtain a valid measurement, therefore it may be difficult to measure in cold or hypotensive patients.

CAPNOGRAPHY (ETCO2) WAVEFORM	CHARACTERISTICS	CONSIDERATIONS
	**Cuff Leak** Waveform degrades sharply	• Check ET Tube for leak and replace as necessary (recommend exchange over a bougie)
	**Curare Cleft** Cleft or notch in waveform	• Represents asynchronous ventilation • Reassess patients level of sedation and augment as needed
	**Obstruction** Classic shark fin pattern	• Represents bronchospasm or airway obstruction • Assess for Hx of asthma, kinked ET tube, foreign body in airway or other anatomical airway obstruction.
	Loss of Waveform Normal waveform and then no waveform	• Assess for total airway obstruction, apnea, or cardiac arrest. • Assess ET tube for dislodgement and/or the need for suction • Check equipment for failure
	**Increasing $ETCO_2$** Waveform increases in amplitude and width	• Assess for insufficient respirations, if breathing spontaneously, and treat underlying cause • Assess for respiratory failure • Assess for temperature increase • Consider increasing minute ventilation • Note: TQ release and sodium bicarbonate may cause a temporary increase in $ETCO_2$
	**Decreasing $ETCO_2$** Waveform decreases in amplitude and width	• Assess for tachypnea and treat underlying cause, if patient breathing spontaneously, • Assess for pulmonary embolism (If possible)

APPENDIX H: PEDIATRIC CONSIDERATIONS

PEDIATRIC CONSIDERATIONS FOR MSMAID & AIRWAY MANAGEMENT

MSMAID:

Similar to adult patients, the same preparatory steps should be followed prior to pediatric airway intervention. There are, however, significant differences with respect to equipment requirements and provider skill level. The core principles of MSMAID remain the same, with the following considerations:

- **Machine** – Continuous ventilation requires specific rate and volume based on the patient's age/size. Ensure your equipment (ventilator) and/or BVM can provide the required rate and volume prior to intubating or performing advanced procedures.[1,2]
- **Suction** – Similar to adults, ideally you can provide in-line suction, but you also will at a minimum need the correct size tubes to be able to provide suction
- **Monitor** – having pediatric sized equipment is essential as well as being able to adapt to pediatric sizes using adult monitors
- **Airway** – Multiple sizes of tubes are essential and proper pre-mission logistic planning includes pediatric supplies
- **Intravenous access** – Ensure you have pediatric sized needles with 24, 22, 20 and 18g as the primary access based on age of the patient. Pediatric intraosseous needles may be required.
- **Drugs** – Ensure you have a drug estimation guide, but always double check pediatric weight-based doses and measurements.

ADDITIONAL EQUIPMENT

1. Broselow Tape or similar height-based treatment aids.[3]
2. Video Laryngoscopy (VL) –VL has been shown in studies to out-perform direct laryngoscopy in pedatric airways.[4-7]
3. Pediatric Kit – Pediatric airway equipment should be pre-packaged and set apart to allow for a rapid inclusion or addition to baseline airway kits.

ESSENTIAL MEASUREMENTS AND FORMULAS

Unlike adult airways that are narrowest at the level of the vocal cords (and therefore visible during DL or VL) pediatric tracheas are narrowest at the infraglottic level (19). In consideration of this, the following formulas and treatment aids are presented to best estimate tube sizes and measurements:

1. ETT size: age/4 +3.5. [8]
2. ETT insertion depth (for children over 1 year of age) in centimeters: age/2 + 13
3. ETT insertion depth (for children under 1 year of age) in centimeters: weight/2 + 8
4. Tidal volume: 5-8 cc/kg, rate concordant with pre-arrest breathing or rate prior to intervention. PALS recommends initial rate of at least 10-12 breaths/minute.[1,2]
5. Use caution with BVM, especially if improvising with adult BVM. Inflate gently only until the chest begins to rise. Surgical Airway Management

LMAs should be the first choice in all children prior to consideration of surgical intervention. Surgical airways should NOT be attempted on children younger than 12 years of age given the maturity of the

thyroid cartilage and the cricothyroid membrane. It should never be attempted in children where the thyroid cartilage cannot be palpated. For children needing advanced airway intervention younger than 12 years of age, a combination of bag-valve-mask ventilation or placement of a supraglottic airway is recommended.[9,1]

APPENDIX I: AIRWAY MANAGEMENT (USING MSMAID) IN PROLONGED FIELD CARE: SUMMARY TABLE

GOAL/CAPABILITY	MINIMUM	BETTER	BEST
MACHINE: Equipment needed post-intubation	Bag-Valve-Mask (BVM) with PEEP valve	• Automated portable ventilator (preferably with PEEP) • Oxygen concentrator	• Full-feature portable ventilator (e.g.; several ventilatory modes, PEEP) • Supplemental oxygen if available
SUCTION	• Improvised suction, such as using syringe + nasopharyngeal airway (NPA) • Patient positioning if not contraindicated	• Manual suction bulb with adapter	Powered commercial suction with oral tip In-line endotracheal tube suction adapter
MONITOR: Monitoring and telemedicine support	• Pulse oximeter (SpO2) • Assistant to monitor respirations and record manual vital signs • Trending vital signs documentation • Voice or data connections to perform telemedicine communication	• Portable Capnometry ($ETCO_2$) /capnography in addition to SpO2 • Transmit photographs from smartphones or personal devices to augment telemedicine communications	• Automatic vital signs monitor with SpO2, $ETCO_2$/waveform capnography, +/- electrocardiogram (EKG) • Synchronous (real-time continuous) telemedicine using video or remote patient monitoring systems
AIRWAY	Ketamine cricothyroidotomy	Add ability to provide continuous sedation	Add a responsible rapid-sequence intubation capability (to include chemical paralysis) with airway maintenance (to include suction) and continuous sedation
AIRWAY: Verify proper tube placement	• Visualization of the tube passing through the vocal cords (in the case of endotracheal intubation) • Auscultation of epigastric region (should be silent) and bilateral lung sounds (should be present) • Colorimetric capnography + endotracheal detection device (EDD) • Easy bilateral rise and fall of the chest + misting of the tube + no signs of gastric insufflation	• Minimum plus portable capnometer • Ultrasound if trained/available to guide and/or verify placement	Continuous $ETCO_2$/waveform capnography
IV/IO ACCESS	• If IV/IO attempts fail or when unavailable: medication may be given intramuscularly or intranasally for immediate sedation to facilitate surgical cricothyroidotomy • Continue attempts at IV/IO access after airway has been controlled	1-2 patent IV/IO	2-3x patent intravenous (IV) / intraosseous (IO) with additional IO device on standby

GOAL/CAPABILITY	MINIMUM	BETTER	BEST
DRUGS: Airway placement	• Local anesthetic for cricothyroidotomy (superficial skin anesthesia plus 1-2 mL injected through the cricothyroid membrane) • Placement without medications in unconscious patient • Also: most sedating agents can be given IM if IV/IO has not been established	Any IV/ IO sedating agent (i.e. opioid, benzodiazepine)	• Procedural dose ketamine (1-2 mg/kg IV push) for ETT or cricothyroidotomy placement • Local anesthetic (lidocaine) for cricothyroidotomy placement
DRUGS: Prolonged sedation (post-placement)	No I.V. access: ketamine (sedation dose), 3-4mg/kg IM	IV/ IO pushes of ketamine, opioid, and/or midazolam (alone or in combination as per the individual's scope of practice, experience and availability of medications)	• Ketamine I.V./ IO Drip • Hydromorphone or alternate opioid IV/IO push for breakthrough pain • Midazolam IV/IO push as needed for sedation
Airway Equipment	• Nasopharyngeal airway • Cricothyrotomy kit • BVM with PEEP valve	• Minimum PLUS supraglottic airway • Gum elastic bougie to facilitate intubation • Nasogastric/orogastric tube	• Better PLUS endotracheal tubes • Video laryngoscopy equipment preferred (direct laryngoscope only if video equipment not available).
Waveform Capnography	Colorimetric $EtCO_2$ detector	Portable capnometer	Waveform capnography on patient monitor

APPENDIX J: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Airway Management of Traumatic Injuries

To optimize the airway management for patients with traumatic injury in the operational medical treatment facility environment.

Appendix A : Trauma AirWay Assessment 5
Appendix B: Difficult Airway Management Algorithm 6
Appendix C: Additional Information Regarding Off-label Uses in CPGs 7

BACKGROUND

Airway obstruction was the second most common cause of potentially survivable death in all US combat casualties from October 2001 to June 2011. Thus, airway management is often a critical early step in the resuscitation of the severely injured trauma patient. Identifying harbingers of a potentially difficult airway, having knowledge of a difficult airway algorithm, and understanding the proper utilization of alternative airway devices will allow for a pre-planned strategy for successful airway management.

SIGNIFICANT CHANGES

Refer to in Appendix A for Trauma Airway Assessment guidance and Appendix B for Difficult Airway Management.

1. Ketamine is the first line agent for Rapid Sequence Intubation (RSI).
2. Apply principles of Apneic Oxygenation.
3. Utilize device name rather than brand-name wherever possible.
4. Eliminate blind nasal intubation. Anticipate fiber optic guidance if available.
5. Use waveform or digital capnography as primary tool to verify tube placement if available.
6. Remove recommendation for use of an intubating Laryngeal Mask Airway.
7. Offer surgical cricothyroidotomy or tracheostomy as surgical airway options.
8. Optimize RSI and Intubation Pathway for all patients. Separate Traumatic Brain Injury (TBI) algorithm not required.
9. Include specific pediatric recommendations.
10. Trauma airway management should be rehearsed with your trauma team on a regular basis to include role assignments and familiarization with difficult airway management and surgical airway equipment.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

- All patients who received ETT/cricothyroidotomy/supraglottic airway/NPA
- All patients with compromised airway (initial GCS < 8 or AIS head and neck ≥ 3 or AIS face ≥ 3, arrival/transport or initial ED SpO2 < 90%, arrival/transport or initial ED ETCO2 > 50).

INTENT (EXPECTED OUTCOMES)

- All injured patients who present with obtundation (GCS<8), apnea, respiratory distress or insufficiency, airway obstruction, or impending airway loss will have a secure and definitive airway established expeditiously upon arrival to a Role 2 or Role 3.
- SpO2 is maintained between ≥ 90% and 96%. SpO2 >96% is not necessary.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who had a secure and definitive airway (endotracheal tube, cricothyroidotomy, tracheostomy) established or verified on arrival to Role 2 or 3, or documentation of appropriate intervention.

2. Number and percentage of patients in the population of interest with initial ED SpO2 < 90%, < 80%, <70%, <60%.

3. Number and percentage of patients who had definitive airway (endotracheal tube, cricothyroidotomy, tracheostomy) with ETCO2 documented at the same role of care where the procedure is done.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional performance improvement monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by JTS Chief and the JTS PI Branch.

RESPONSIBILITY

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

All Health Care Providers

1. Will be familiar with the guidelines for performance of trauma airway management.
2. Will be familiar with the guidelines for performance of rapid sequence intubation.
3. Will be familiar with alternative airway devices mentioned in guidelines for trauma airway management.
4. Will provide feedback and suggested CPG changes to the JTS Chief and/or Program Manager.

The Chief, Emergency/Anesthesia/Surgery

At each Level III facility, the chief will coordinate with the JTS Chief on the appropriateness of the guidelines being used and provide input for updates on an as needed basis.

The JTS Chief

1. Will be the subject matter expert on the trauma airway management CPG to be used in the US Central Command Area of Responsibility.
2. Will review annually and update the CPG as needed.

APPENDIX A : TRAUMA AIRWAY ASSESSMENT

Trauma Airway Management

Airway Assessment

- All trauma airways are potentially high-risk. Anticipate a difficult airway.
- Identify critical team members and verbalize role assignments.
- Initiate pre-oxygenation (1,2).
- Consider Ketamine (0.5-1.0 mg/kg IV/IO) for delayed sequence intubation if combative or otherwise uncooperative patient (3,4,5).
- Recall that the neutral position ("C-spine stabilization") degrades the laryngoscopic view.

Rapid Sequence Induction (RSI) and Intubation Pathway

1. **Confirm equipment availability and function.**
   IV/IO, suction, self-inflating bag and mask, oxygen source, laryngoscope- video (preferred) or direct (if video not available) (5, 20), ETT with stylet and/or gum elastic bougie, oral & nasal airways, surgical airway kit, drugs, C02 detector, monitors, other rescue equipment
2. **Pre-Oxygenate (Denitrogenate) the lungs (1,2,6)**
   - Prolongs tolerance of apneic period
   - Goal is ≈ 3 minutes of tidal volume breathing at 90% FiO2.
   - With standard reservoir facemask set flow rate of oxygen as high as possible
   - Recommend augmenting with nasal cannula at 15L/min oxygen in preparation for apneic oxygenation, leave in situ throughout procedure (2,8)
   - Elevate head of bed if not contraindicated.
3. **Maintain cervical spine stabilization.**
4. **Remove front of cervical collar**
5. **Consider cricoid pressure simultaneous w/ medication administration (9,10)**
6. **Administer medications :** Initiate RSI

Sedative/hypnotic

- Ketamine (1st Line): 2 mg/kg IV/IO
- Etomidate (2nd Line): 0.3 mg/kg IV/IO

Unstable patients require reduced dosage of induction agent.

Neuromuscular Blockade

- Rocuronium: 1.2 mg/kg IV/IO or
- Vecuronium: 0.1 mg/kg IV/IO or
- Succinylcholine: 1.5 mg/kg IV/IO

7. **Perform laryngoscopic tracheal intubation.**
   - Following onset of neuromuscular blockade
   - Recommend gum elastic bougie as primary ETT stylet.
8. **If laryngoscopic view is poor:**
   - Apply external laryngeal manipulation technique(s)
   - Consider alternative visualization method or Supraglottic airway device.
9. **Confirm tracheal intubation.**
   - Visualize tube passing between the vocal cords (First Line)
   - Wave form or digital capnography when available (Second Line)
   - Easy chest rise, equal axillary breath sounds/absence of gastric insufflation, CO2 Calorimeter, and "fog" in ETT
   - Esophageal detector bulb or fiber optic confirmation during cardiac arrest
10. **Provide continuing care IAW Anesthesia CPG**

Recommendations for Pediatric Patients

1. Train to expect pediatric patients. Have a dedicated pediatric airway cart, including Broselow tape or equivalent.
2. Pre-dose with atropine IV/IO (0.02mg/kg, minimum dose 0.1mg, maximum dose 0.5mg) in all <1 years old, those <5 who are receiving succinylcholine, and in all who receive a 2nd dose of succinylcholine.
3. Induction -
   - Ketamine (first line) 2mg/kg IV/IO
   - Etomidate (second line) 0.3mg/kg IV/IO
4. Neuromuscular blockade -
   - Succinylcholine 1.5mg/kg IV/IO (2mg/kg <5 years old) or
   - Rocuronium 1mg/kg IV/IO
5. Avoid surgical airway in <12 years old - use needle cricothyroidotomy (12-14 gauge), tracheostomy preferred over surgical cricothyroidotomy

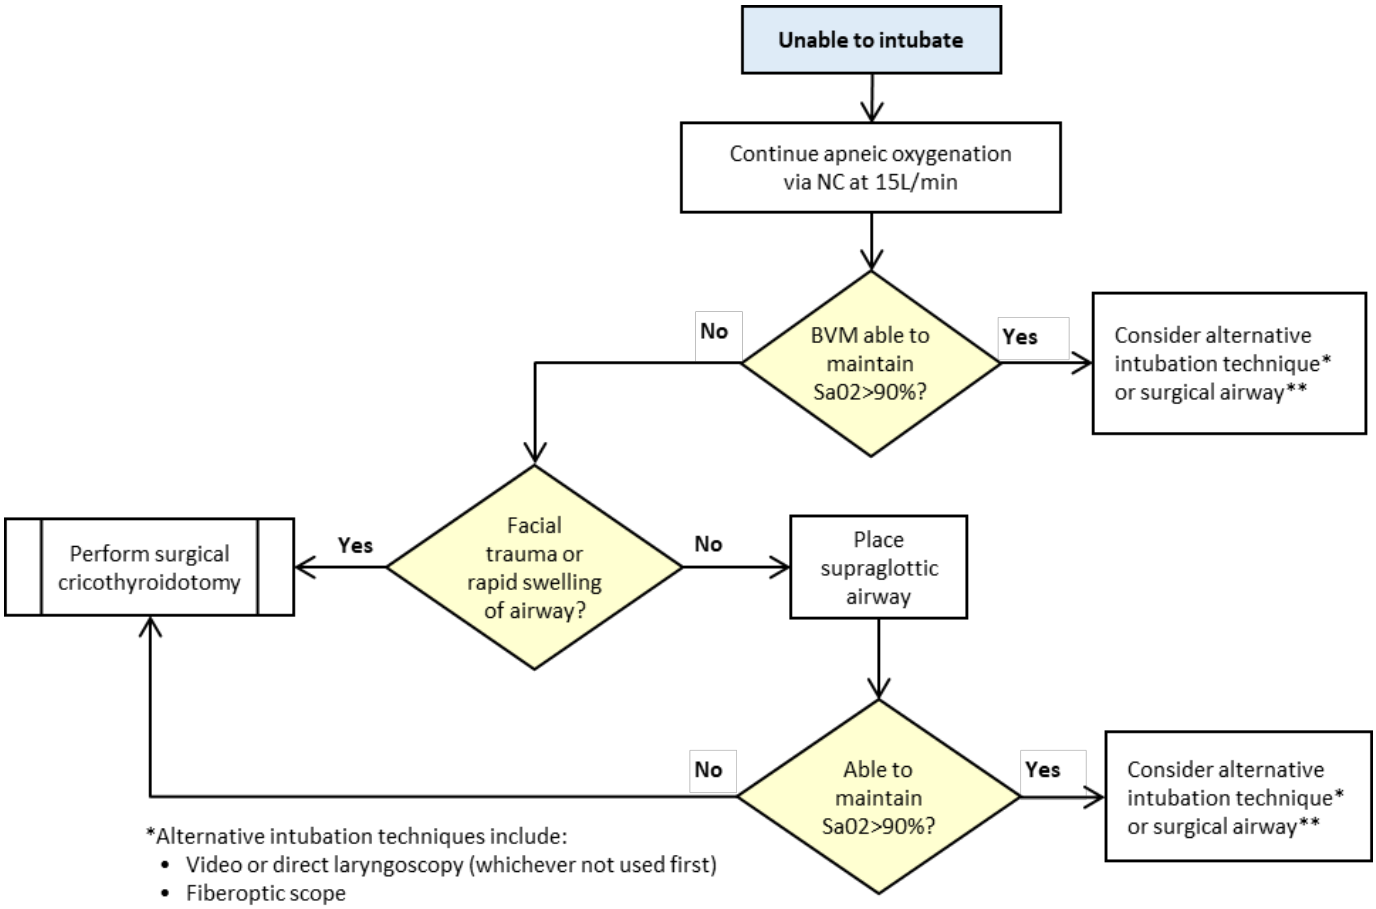
Unable to Intubate: Can You Mask Ventilate?

Mask Ventilation Pearls

- Skilled operator
- Good seal
- Jaw thrust
- Oral airway
- Nasal airway(s)
- Two operator mask ventilation

YES	• Improve position, change blade/operator, laryngeal manipulation technique, gum elastic bougie. • Attempt alternate technique: Fiber optic, video laryngoscope, tracheal trans illumination device. • More than ≈ 3 attempts at intubation may abolish your ability to mask ventilate due to edema caused by laryngoscopy. • Surgical airway (Cricothyroidotomy or tracheostomy)
NO	• Emergency pathway...seconds matter. • Supraglottic airway or • Surgical cricothyroidotomy

APPENDIX B: DIFFICULT AIRWAY MANAGEMENT ALGORITHM



*Alternative intubation techniques include:

- Video or direct laryngoscopy (whichever not used first)
- Fiberoptic scope
- Transtracheal illumination device
- Retrograde wire with Magill forceps
- Changing providers

**Surgical airway includes both tracheostomy and surgical cricothyroidotomy will be performed.

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Amputation: Evaluation and Treatment (CPG ID: 07)

To provide standardization of optimal care for the performance of wound management and life-saving amputations that will ensure preservation of maximum limb length, promote healing of viable tissues, and facilitate optimal rehabilitative function.

Appendix A: Additional Information Regarding Off-label Uses n CPGs 7

BACKGROUND

The extent of the "zone of injury" is dependent upon the mechanism of injury (i.e. blast, gunshot and crush injuries), as well as the co-morbidities and physiologic status of the casualty. Factors such as severe blood loss with massive resuscitation, burns, compartment syndrome, tourniquet use, and contamination load often extend the actual amount of tissue damage beyond that which is apparent on initial visual inspection.[1] Amputation terminology includes traumatic amputations which are immediate extremity amputations caused by the wounding mechanism itself. Primary amputations are those performed by a surgical team after evaluation of the mangled extremity, with the decision not to pursue limb salvage for whatever reason. Secondary amputations can occur early (within 90 days) or late (after 90 days), with the latter referring to those amputations occurring after an initial attempt at limb salvage has been undertaken. Most commonly, primary and early secondary amputations are performed for vascular injuries not amenable to repair or resulting in prolonged limb ischemia, nerve injuries not compatible with a functional extremity, or extensive nonviable tissue with potential for uncontrolled sepsis. Late secondary amputations are generally performed due to patient preference or major complications (e.g., flap failure, recurrent osteomyelitis, persistent poor function or pain) of attempted limb salvage. Current consensus regarding extremity amputation following battle-injury is to preserve limb length and vascularity, facilitate adequate wound drainage, and achieve eventual coverage and closure of the amputation wound.[2]

DECISION TO AMPUTATE

Although a number of scoring systems to predict the need for amputation exist,[3] none is widely accepted or validated in the combat trauma population. Intact or the potential to restore perfusion (by vascular repair or shunt) may be the first determinant. If perfusion can be restored, any decision regarding amputation for nerve or bone loss can potentially be deferred until later, with the structurally unstable limb for transport by splinting or external fixation. Given the time sometimes required to restore perfusion, amputation may be necessary and a Damage Control procedure in a massively injured patient.

EVALUATION AND TREATMENT

1. Thorough **inspection of the wounds** with liberal use of surgical wound extension is necessary to inspect all levels of tissue including examination of fascial planes. If available, continuous wave Doppler examination and diagnostic arteriography can be used as adjuncts in cases where distal perfusion is a concern.[4]

2. **After early control of active hemorrhage** is achieved, gross decontamination, followed by a meticulous sharp debridement using a scalpel and/or scissors should be a starting point for nearly all wartime penetrating wounds. Removal of all nonviable tissue, including skin, fat, fascia, muscle, and bone, is essential to reduce the load of contamination and necrotic tissue in the wound and is the hallmark of an adequate debridement. The adjunct of irrigation or lavage with normal saline is also important to decrease bacterial count and soiling. This can be accomplished using various devices such as pulse lavage using a battery powered system or gravity irrigation using genitourinary tubing or bulb/syringe. Published clinical data is inconclusive as to which irrigation method is superior (see Initial Management of War Wounds JTS CPG for additional information). Assurance of hemostasis is important prior to evaluation for dressing or closure.[5]

3. **In the setting of an extremity amputation**, appropriate vascular structures should be ligated proximal to the bone resection but as distal as possible to ensure adequate tissue perfusion. Vascular structures should be separated from nerves prior to ligation.

4. **The amputation should be performed at the most distal level which provides viable bone and soft tissues for later closure**. In select instances close to the proximal joint (e.g. knee, elbow), preservation of viable bone length in the absence of adequate viable soft tissue coverage is advocated in order to preserve options for either late free tissue transfer coverage and amputation level salvage or disarticulation. Ipsilateral fractures proximal to the level of viable tissue should be initially stabilized and should not be a determining factor for amputation level. These fractures can be stabilized with external fixation, splinting, or pins to facilitate evacuation.[6]

5. Be prepared to **accept atypical skin and tissue flaps** so long as the tissue is viable.

6. **Do not perform primary closure of traumatic amputations.** All wounds must be left open and re-evaluated with serial irrigation and debridement's as the zone of injury declares itself.

7. **Avoid open circular or guillotine amputations.** These techniques are antiquated, sacrifice viable soft tissue and relegate the casualty to more proximal revision, and are not that much faster than the open, length-preserving length of initial amputation advocated. All amputations should be performed at the most distal level practicable with re-evaluation of the open amputation site within the first 24 hours.[7,8]

POST-OPERATIVE MANAGEMENT

1. **Soft dry dressing should be applied around the amputation site and extremity**. Circumferential wraps with gauze rolls and ace wraps must be applied in a figure of eight fashion without excessive compression.

2. The limb **may be placed in a splint or bivalve cast** to prevent joint contractures and provide soft tissue support when necessary. There should be simple access for wound inspection.

3. In the **event of the short skin flaps**, skin traction to prevent soft tissue retraction is an option.

4. **Avoid placement of pillows under the knee** so as to prevent contractures when dealing with amputations below the knee.

5. **Negative Pressure Wound Therapy (NPWT) device using Reticulated Open Cell Foam (ROCF)** material, have recently been shown to be an alternate strategy and valuable adjunct in the overall management of amputation wounds.[9] The Vacuum Assisted Closure (VAC) device has been the primary NPWT device used within the DoD. Recent clinical studies support the use of the VAC as a soft tissue wound management adjunct in appropriately prepared wounds as a bridge to delayed closure, flap coverage, or coverage with a split thickness skin graft. In appropriately debrided and prepared wounds the VAC has been shown to increase the rate of granulation and decrease bacterial colonization leading to effective amputation coverage and or closure.[10] Use of NPWT/ROCF should be considered only after complete wound debridement and hemostasis have been achieved. The VAC ROCF sponge should cover the open wound bed and be set to -125 mm Hg continuous pressure.[4]

   NOTE: *Use of VAC dressings has recently been demonstrated to be safe in patients during strategic aeromedical evacuation.*

   The efficacy and long-term sequelae of NPWT/ROCF is not yet fully established, however; current clinical experience has been largely favorable. Surgeons who elect to employ this wound coverage method as part of their overall wound management strategy should be thoroughly familiar with the VAC system and its correct use.

6. There are **disadvantages to the use of NPWT** in the management of combat-related amputations: they are bulky for transport and can easily occlude or leak, resulting in ineffective therapy or the machine

shutting down automatically during transport. Additionally, NPWT can macerate tissue, obliterate soft tissue planes, and there is concern for a potential role in the pathogenesis of heterotopic ossification.

7. **NPWT/ROCF dressings can be left in place for 24 to 48 hours** depending upon the extent and acuity of the wound. More extensive and acute soft tissue wounds should have the VAC dressing removed with further irrigation and debridement on shorter intervals (every 24 hours) compared to less extensive wounds (greater than every 24 hours). Initiation of delayed primary closure from the ends of the wound may be started during these repeat debridements and irrigation with re-application of smaller VAC dressing sponges.

8. **Coordinate dressing changes/repeat debridement with evacuation schedule** to avoid extended periods without wound care or inspection. Given the extent of many soft tissue wounds dressing changes and repeat debridements should be performed in the operating room affording the patient the comfort of conscious sedation or general anesthesia and the surgeon access to the full array of equipment necessary to perform adequate debridement. Also, reapplication of the VAC dressing may be more complete and effective if performed in the operating room with the support of operating room and anesthesia teams.

AEROMEDICAL EVACUATION CONSIDERATIONS

Due to the requirement to move the coalition patient with traumatic amputation to Role 4 facilities usually out of theater, early and safe transport of these patients should involve consideration of the following factors.

1. **Concomitant injury management** is crucial during flight. Additional orthopedic injuries should be stabilized and structurally sound for transport. Limbs should be splinted and positioned to decrease the possibility of post traumatic contractures.

2. If **adequate tissue perfusion** is a concern, supplemental oxygen should be given to increase oxygen tissue delivery.

3. **Large wounds or wound vacuums** can add an area of increased heat loss. Take preventative measures to reduce risk of hypothermia.

4. **Flight stresses** include movement and vibration which can increase pain during transport. It is likely that pain medication requirements will increase during these times. Evaluate analgesia protocols as well as the patient's analgesia needs and response to pain medications.

5. ***Do not remove drains or wound vac*** in the immediate period prior to aeromedical evacuation. Coordinate dressing change timing with the patient movement schedule.

6. **Patients with multiple trauma** require Deep Vein Thrombosis prophylaxis if anatomically feasible and not contraindicated. Refer to The Prevention of Deep Vein Thrombosis-Inferior Vena Cava Filter CPG, 02 Aug 2016 (ID:36) for specific guidance.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients with diagnosis of limb amputation or limb amputation procedure code.

INTENT (EXPECTED OUTCOMES)

1. Amputation wounds are not closed at the initial operation
2. Circular/guillotine amputation is avoided (viable soft tissue is preserved).
3. Repeat debridement/dressing change within 48 of first debridement/amputation procedure.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who have amputation wounds left open at initial operation (closed flap amputation at first procedure = non-adherence).
2. Number and percentage of patients in the population of interest who have documentation that all viable soft tissue is preserved at the initial operation.
3. Number and percentage of patients in the population of interest who have their dressing change/repeat debridement in <48 hours of initial amputation/procedure.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Analgesia and Sedation Management during Prolonged Field Care

The intent of this guideline is to identify potential issues one must consider when providing analgesia with or /without sedation for an extended time. This guideline begins where Tactical Combat Casualty Care (TCCC) guidelines end.

PURPOSE

This Role 1, prolonged field care (PFC) guideline is intended to be used after Tactical Combat Casualty Care (TCCC) Guidelines, when evacuation to higher level of care is not immediately possible. A provider of PFC first must be an expert in TCCC. The intent of this guideline is to identify potential issues one must consider when providing analgesia with or without sedation for an extended time (i.e. 4–72 hours). As a principle, the guideline attempts to decrease complexity by reducing options for monitoring, medications, and so forth. It prioritizes experience with a limited number of options rather than providing recommendations about many different options that can be used in a more customized way. It does not address induction of anesthesia before airway management (i.e. rapid sequence intubation). The CPG should be used by all clinicians providing analgesia and sedation in a Role 1 (R1) or PFC environment.

PRIORITIES OF CARE

Priorities of care as related to analgesia and sedation:

1. Keep the casualty alive. Do not give analgesia and/or sedation if there are other priorities of care (e.g., hemorrhage control).
2. Sustain adequate physiology to maintain perfusion. Do not give medications that lower blood pressure or suppress respiration if the patient is in hemorrhagic shock or respiratory distress (or is at significant risk of developing either condition).
3. Relieve pain. Give medications to treat pain first.
4. Maintain safety. Agitation and anxiety may cause patients to do unwanted things (e.g., remove devices, fight, fall). Sedation may be needed to maintain patient safety.
5. Stop awareness. During painful procedures, and during some mission requirements, amnesia may be desired.

PRINCIPLES

- In an R1 or PFC setting, intravenous (IV) or interosseous (IO) medication delivery is preferred over intramuscular (IM) therapies. The IV/IO route is more predictable in terms of dose-response relationship.
- Remember, you can always give more, but it is very difficult to take away. Therefore, it is easier to prevent cardiorespiratory depression by being patient and methodical. **Titrate to effect**.
- Smaller, more frequent doses of medications are preferred to single large doses to achieve a constant level of pain control and sedation over a longer time.
- The lower the blood volume, the less drug and time will be needed to achieve similar affects as compared with a normovolemic patient. **Start low, go slow.**

Engage telemedicine support early and often if you are inexperienced in delivering analgesia and sedation beyond TCCC or if you are having difficulty.

PRINCIPLES OF MEDICATION USE IN THE PFC SETTING

Comparative effectiveness data for one analgesia/sedation strategy versus another are lacking. The principles of medication use in the PFC setting include:

1. Consider pain in three categories:

    a. **Background**: the pain that is always present because of an injury or wound. This should be managed to keep a patient comfortable at rest but should not impair breathing, circulation, or mental status.

    b. **Breakthrough**: the acute pain induced with movement or manipulation. This should be managed as needed. If breakthrough pain occurs often or while at rest, background pain medication should be increased.

    c. **Procedural**: the acute pain associated with a procedure. This should be anticipated and managed periprocedurally.

2. Analgesia is the alleviation of pain and should be the primary focus of using these medications. In other words, treat pain before considering sedation. Remember, not every patient needs (or should receive) pain medication at first, and unstable patients may require other therapies or resuscitation before the administration of pain or sedation medications.

3. Sedation is used to relieve agitation or anxiety and, in some cases, induce amnesia. The most common causes of agitation are untreated pain or other serious physiologic problems like hypoxia, hypotension, or hypoglycemia. Sedation is used most commonly to ensure patient safety (e.g., when agitation is not controlled by analgesia and there is need for the patient to remain calm to avoid movement that might cause unintentional tube, line, dressing, splint, or other device removal or to allow a procedure to be performed) or to obtain patient amnesia to an event (e.g., forming no memory of a painful procedure or during paralysis for ventilator management).

4. Each patient responds differently to medications, particularly with respect to dose. Some individuals require substantially more opioid, benzodiazepine, or ketamine; some require significantly less. Once you have a "feel" for how much medication a patient requires, you can be more comfortable giving similar amounts during redosing. In general, a single medication will achieve its desired effect if enough is given; however, the higher the dose, the more likely the side effects. Additionally, ketamine, opioids, and benzodiazepines given together have a synergistic effect: the effect of medications given together is much greater than a single medication given alone (i.e. the effect is multiplied, not added. Go with less than what you might normally use if each were given alone).

5. PFC requires a different treatment approach than TCCC. Go slow, use lower doses of medication, titrate to effect, and redose more frequently. This will provide more consistent pain control and sedation. High doses may result in dramatic swings between oversedation with respiratory suppression and hypotension alternating with agitation and emergence phenomenon.

MONITORING

Patients receiving analgesia and sedation require close monitoring for life-threatening side effects of medications.

- **Best:** Portable monitor providing continuous vital signs display and capnography; document vital signs trends frequently.
- **Better:** Capnography (if controlled airway) in addition to minimum requirements.
- **Minimum:** Blood pressure cuff, stethoscope, pulse oximeter; document vital signs trends.

MEDICATIONS

NOTE: *Use the PFC Analgesia and Sedation Guideline table (Appendix A) for recommended treatments.*

- *Ketamine drip recommendations are detailed in Appendix B.*
- *A "cheat sheet" of common IV medications is listed in Appendix C.*
- *Providers using these guidelines should be intimately familiar with the medications in Appendix D, including their pharmacology, and side-effects.*

The PFC Analgesia and Sedation Guideline table in Appendix A is arranged according to anticipated clinical conditions, corresponding goals of care, and the capabilities needed to provide effective analgesia and sedation according to (1) the minimum standard, (2) a better option when mission and equipment support is available (all medics should be trained to this standard), and (3) the best option that may only be available in the event a medic has had additional training and experience, and/or equipment is available. The table is intended to be a quick reference guide but is not stand alone: you must also know the information in the rest of the guideline.

Medications in the table are presented as either Give or Consider.

- **Give:** Strongly recommended.
- **Consider**: Requires a complete assessment of patient condition, environment, risks, benefits, equipment, and provider training.

Step 1. *Identify the clinical condition.*

- **Standard analgesia** is for most patients. The therapies used here are the foundation for pain management during PFC. Expertise in dosing oral transmucosal fentanyl citrate (OTFC) and augmenting it with low dose ketamine IV or IO is a must.
- **Difficult analgesia or sedation needed** is for patients in whom standard analgesia does not achieve adequate pain control without suppressing respiratory drive or causing hypotension, OR when mission requirements necessitate sedating a patient to gain control over his/ her actions to achieve patient safety, quietness, or necessary positioning.
- **Protected airway with mechanical** ventilation is for patients who have a protected airway and are receiving mechanical ventilatory support or are receiving full respiratory support via assisted ventilation (i.e., bag valve).
- **Shock present** is for patients who have hypotension and shock.

Step 2. *Read down the column to the row representing your available resources and training.*

Step 3. *Provide analgesia/sedation medication accordingly.*

Step 4. *Consider using the Richmond Agitation-Sedation Scale (RASS) score (Appendix F) as a method to trend the patient's sedation level.*

For IV/IO drip medications:

- Use normal saline to mix medication drips when possible, but other crystalloids (e.g., lactated Ringer's, Plasmalyte, and so forth) may be used if normal saline is not available.
  - DO NOT mix more than one medication in the same bag of crystalloid because this practice has not been studied and may not be safe. Mixing medications together, even for a relatively short time, may

cause changes to the chemical structure of one or both medications and could lead to toxic compounds. There is ongoing research to determine the safety of such practices.

- If a continuous drip is selected, use only a ketamine drip in most situations, augmented by push doses of opioid and/or midazolam if needed. Multiple drips are difficult to manage and are generally not recommended. Multiple drips should only be undertaken with assistance from a telemedicine consultant with critical care experience. Multiple drips are most likely to be helpful in patients who remain difficult to sedate with ketamine drip alone and can "smooth out" the sedation (i.e., fewer peaks and troughs of sedation with corresponding deep sedation mixed with periods of acute agitation).

REGIONAL ANESTHESIA

(Appendix E)

Regional anesthesia (e.g., local anesthetic such as ropivacaine or lidocaine injected adjacent to a large, extremity nerve bundle or on either side of a finger or toe) is a useful technique that can markedly reduce or eliminate limb pain without risk of opioid or benzodiazepine side-effects of respiratory depression, sedation, and hypotension. There are, however, serious potential morbidities (and mortality from proximal injections or injection directly into blood vessels) that may occur.

For these reasons, this guideline has attempted to balance the overall risks and potential benefits of this intervention by recommending optimal procedure technique (e.g., use of ultrasound), a limited number of block sites, and the safest medication and dose combination. It should be noted that even with optimal technique, the risk of systemic toxicity (e.g., seizure or cardiac arrest) is not eliminated. Toxicity occurs either with direct injection of anesthetic into the systemic blood circulation or by absorption over the first 15–20 minutes after injection. Close monitoring MUST be available during this time.

Regional anesthesia should only be used by trained individuals. There should be documentation of competency. Three techniques exist:

1. **Ultrasound-guidance:** used to visualize targeted nerves, needle placement, and the spread of local anesthetic in real time.
2. **Nerve stimulation:** requires an assistant, a nerve stimulator, specialized needles, and cannot be reliably applied in cases of partial or complete amputations, given the inability to elicit motor response in severed muscles.
3. **Blind or anatomical technique:** should be reserved for distal nerve blocks only (i.e. fingers or toes).

ANALGESIA AND SEDATION FOR EXPECTANT CARE (I.E. END- OF –LIFE CARE)

An unfortunate reality of our profession, both military and medical, is that we encounter clinical scenarios that will inevitably end in a patient's death. In these situations, it is a healthcare provider's obligation to give palliative therapy to minimize the person's suffering. In these circumstances, the use of opioid analgesics and sedative medications is therapeutic and indicated, even if these medications worsen a patient's vital signs (i.e., cause respiratory depression and/or hypotension). If a patient is expectant:

Call a telemedicine consult.

- **Prepare** to

  - Give opioid (morphine is preferred, but hydromorphone, fentanyl, or other opioid can be given) until the patient's pain is relieved. If the patient is unable to communicate their pain, give opioid medication until the respiratory rate is less than 20/min.
  - If the patient complains of feeling anxious (i.e. is worrying about the future but not complaining of pain) or he cannot express himself but is agitated despite having a respiratory rate less than 20/min, give a benzodiazepine until the anxiety is relieved or the patient is sedated (i.e. is not feeling anxious or is no longer agitated).
- **Position** the patient as comfortably as possible. Pad pressure points.
- **Provide** anything that gives the patient comfort (e.g., water, food, cigarette).
- **Relief** of suffering, primarily through pain relief, is the goal during expectant care.

Call a telemedicine consult to discuss.

ABOUT THE AUTHORS

LTC Pamplin, USA, is a board-certified intensivist and is currently the director of Virtual Critical Care at Madigan Army Medical Center, Joint Base Lewis-McChord, Washington. Previously, he was the director of the US Army Burn Intensive Care Unit and chief of Clinical Trials in Burns and Trauma at the US Army Institute of Surgical Research, San Antonio, Texas. He has served as the Simulation and Training Director for the Extracorporeal Membrane Oxygenation Program, San Antonio Military Medical Center, and the director of the Surgical Intensive Care Unit, Brooke Army Medical Center.

MAJ Fisher, USAR, is a first-year medical student at Texas A&M College of Medicine and assigned to the 7249th MSU, Houston, Texas. He was previously assigned to the 75th Ranger Regiment, where he served as a battalion and regimental physician assistant.

SFC Penny, USA, is a senior medic and instructor at the Special Operations Combat Medic Course, US Army John F. Kennedy Special Warfare Center and School.

SFC Olufs, USA, is a Special Forces Medical Sergeant, currently serving as noncommissioned officer in charge of Emergency Medicine at the Joint Special Operations Medical Training Center. He has previously served as a Special Forces Operational Detachment-A Senior Medical Sergeant on four deployments to the Central Command Area of Operations with 5th Special Forces Group.

SFC Rapp, USA, is assigned to the Office of Special Warfare as the NCOIC for Unconventional Warfare Medicine Research.

Dr Hampton is a board-certified emergency physician with additional fellowship training in emergency ultrasonography. She is an avid medical educator and a volunteer subject matter expert and ultrasound instructor for the military medical community. Dr Hampton is currently practicing at the Landstuhl Regional Medical Center, Germany (US Army Medical Department).

MAJ Powell, USA, is a board-certified intensivist. He is currently the 4th Battalion, 3rd Special Forces Group (Airborne) surgeon and staff intensivist at Womack Army Medical Center, Fort Bragg, North Carolina. He serves on the Prolonged Field Care Working Group as chair of the research subcommittee and a member of the telemedicine subcommittee.

COL Keenan, USA, is a board-certified emergency medicine physician, and is currently serving as Command Surgeon, Special Operations Command, Europe. He has previously served as Battalion Surgeon in both 1st and 3rd SFG(A), and as Group Surgeon, 10th SFG(A). He is the coordinator for the SOMA Prolonged Field Care Working Group.

Col Shackelford, USAF, is a trauma surgeon, currently serving as the chief of Performance Improvement, Joint Trauma System, San Antonio, Texas. She is a member of the Committee on TCCC and has previously deployed as the director of the Joint Theater Trauma System.

APPENDIX A: PFC ANALGESIA AND SEDATION GUIDELINE

Step 1. Identify the clinical situation on the top row.
Step 2. Read down the column to the row representing your available resources and training.
Step 3. Provide analgesia/sedation medication accordingly.

	Standard Analgesia *(Most Patients)*	**Difficult Analgesia or Sedation Needed** *(e.g., Polytrauma/Litter Bound/Mission Demand)*	**Protected Airway** *(e.g., Intubated/Cricothyrotomy + Assisted Ventilation*	**Shock Present**
Goal	Minimize pain and anxiety and maintain normal physiology: • Airway – mental status adequate to protect airway (i.e., coughs, not snoring or obstructing airway) • Breathing – adequate ventilation (RR > 12/min, $EtCO_2$ < 50mmHg) and oxygenation (SpO_2 > 96%[1] • Perfusion – systolic blood pressure > 90mmHg	In addition to standard analgesia goals: • Control pain unresponsive to standard analgesia • Achieve quiet, calm casualty who can still be aroused	• Maintain airway device (deep sedation) • Achieve patient-ventilator synchrony • Maintain blood pressure	• Initiate treatment for shock before giving analgesia or sedation • Do not worsen shock
Minimum	• *Give*: acetaminophen 1,000mg PO every 6 hours • *Give*: meloxicam 15mg PO daily • *Give:* OTFC 800µg per TCCC guidelines • *Give*: ketamine push[1] • *Give*: ondansetron 4mg ODT/IV/IO/IM every 4 hours PRN	• *Give*: Standard analgesia *plus* • *Give*: hydromorphone or alternate opioid[2] • *Give*: ondansetron 4mg ODT/IV/IO/IM every 4 hours PRN	• *Give*: ketamine push[1] • *Give*: hydromorphone or alternate opioid[2] • *Give*: ondansetron 4mg ODT/IV/IO/IM every 4 hours PRN	• *Give*: ketamine push[1] • *Give*: ondansetron 4mg IV/IO every 4 hours PRN
Better	• *After initial pain control with OTFC and/or ketamine* • *Give*: acetaminophen/oxycodone (e.g., Percocet; if able to take PO)[2]	• *Give*: Standard analgesia *plus* • *Give*: hydromorphone or alternate opioid[2] • *Give*: midazolam[2]	• *Give*: ketamine push[1] • *Give*: hydromorphone or alternate opioid[2] • *Give*: midazolam[2] • *Give*: ondansetron 4mg ODT/IV/IO/IM every 4 hours PRN	• Same as minimum
Best	• *Give*: Regional nerve block for limb trauma (See Appendix E)	• Standard analgesia plus • *Give*: hydromorphone or alternate Opioid [2,5] • *Give*: midazolam[2] • Consider: ketamine load, then drip (for sedation)[3,4]	• *Give*: ketamine load, then drip (for sedation) [3,4] • *Give*: hydromorphone or alternate opioid [2,5] • *Give*: midazolam[2]	• *Give*: ketamine push[1] OR • Consider: ketamine load, then drip (for sedation)[3,4] If additional sedation needed AND blood pressure will tolerate: • Consider: hydromorphone or alternate opioid [2,5] • Consider: midazolam[2]

1. Ginde AA. Strategy to Avoid Excessive Oxygen (SAVE-O2) in Critically Ill Trauma Patients: A Multicenter Cluster-Randomized, Stepped Wedge Trial for Targeted Normoxemia. Scientific Plenary Presentation (MHSRS-23-10446), Military Health System Research Symposium; August 14, 2023

$EtCO_2$, end-tidal carbon dioxide; IM, intramuscular; IO, intraosseous; IV, intravenous; OTFC, oral transmucosal fentanyl citrate; PO, per os (by mouth); PRN, as needed; RR, respiratory rate; SpO_2, oxygen saturation; TCCC, Tactical Combat Casualty Care.

Note: Lower doses of pain/sedation medications given more frequently are best for steady control. START LOW, GO SLOW.

[1]Ketamine push (for pain): 20mg (range, 0.1–0.2mg/kg) IV/IO every 10–30 minutes PRN. If an IV/IO is not available, quadruple the ketamine dose to give 80mg IM (range, 0.4–0.8mg/kg IM).

[2]To identify the effective dose of pain or sedation medication, give the lowest dose every 2–5 minutes until therapeutic target achieved or maximum dose is given. The effective dose is the amount required to achieve the desired effect (i.e., pain control or sedation). If unable to achieve target with maximum-dose opioid, add midazolam.

- Hydromorphone 0.5mg (range, 0.25–2mg) IV/IO every 1–6 hours PRN (long acting, effective, fewest side-effects)
- ALTERNATIVE opioid:
  - Fentanyl 50µg (range, 25–100µg) IV/IO every 30 minutes to 2 hours PRN (short acting, extremely fast onset, good for severe pain/procedures, greatest risk of respiratory depression)
  - Morphine 5mg (range, 2.5–10mg) IV/IO every 1–6 hours PRN (Long acting, more side-effects)
- Midazolam 1mg (range, 0.5–2 mg) IV/IO every 1–6 hours PRN (sedation, amnesia)
- Percocet 1–2 tab PO every 4 hours PRN (slower onset but provides steady pain control for up to 6 hours). Can supplement with effective dose of IV/IO opioids or ketamine for breakthrough pain. *Contains 650mg acetaminophen. Do not exceed 4,000mg acetaminophen per day.*

[3]***Ketamine loading dose (for sedation): 1mg/kg IV push over 60 seconds, then drip for continuous sedation. See mixture and dosing tables in Appendix B. Ketamine may be used for either pain control or sedation, depending on the dose.***

[4]A continuous ketamine drip may take an hour to take full effect or wear off. Always start with a loading dose and augment with an effective dose of opioid and/or midazolam if additional sedation is needed. Increase or decrease drip gradually.

[5]If breakthrough pain occurs on ketamine drip, give an effective dose of opioid. If effective dose is needed twice in 1 hour, increase drip rate to next higher level. If no breakthrough pain in past 2 hours, decrease drip rate to next lower level.

Note: Consider using the RASS score as a method to trend the patient's sedation level. See Appendix F.

Call telemedicine consult if you are having difficulty managing pain or sedation.

APPENDIX B: KETAMINE DRIP DOSING TABLES

Ketamine drip (for sedation): Sedation loading dose first (1mg/kg IV/IO over 60 seconds).
MIX: 750mg (1.5 vials of 500mg/5mL) in 250mL of normal saline (3mg/mL solution).

Initial drip dose:

- **Best:** Using an IV pump, set to µg/kg/min dose desired. Increase or decrease dose by 5–10µg/kg/min increments.
- **Better:** Using a dial flow adaptor, initial drip rate in mL/h equals the casualty's weight in kg divided by 2 (see mL/h table).
- **Minimum:** Count drip rate. Increase or decrease rate by 1–2 drips/min (very slowly) to achieve goal.

Drip adjustments: Increase or decrease drip by 0.25mg/kg/h (1 row).

Ketamine Drip Dosing Tables

Ketamine drip rate for dial flow or IV pump (starting dose highlighted)

Dose		Patient's Weight, kg			
		40	60	80	100
mg/kg/h	µg/kg/min	Infusion Rate, mL/h			
0.5	8	7*	10	13	17
0.75	13	10	15	20	25
1.0	17	13	20	27	33
1.25	21	17	25	34	42
1.5	25	20	30	40	50
1.75	29	24	35	47	59
2.0	33	27	40	53	67

Ketamine drip count for 15 drips/mL tubing (starting dose highlighted)

		Infusion Rate, 1 drip/X seconds			
0.5	8	1/35	1/24	1/18	1/9
0.75	13	1/27	1/18	1/14	1/8
1.0	17	1/18	1/12	1/9	1/7
1.25	21	1/15	1/10	1/8	1/6
1.5	25	1/12	1/8	1/6	1/5
1.75	29	1/11	1/7	1/6	1/5
2.0	33	1/9	1/6	1/5	1/4

Ketamine drip count for 10 drips/mL tubing (starting dose highlighted)

		Infusion Rate, 1 drip/X seconds			
0.5	8	1/53	1/36	1/27	1/14
0.75	13	1/41	1/27	1/21	1/12
1.0	17	1/27	1/18	1/14	1/11
1.25	21	1/23	1/15	1/12	1/9
1.5	25	1/18	1/12	1/9	1/8
1.75	29	1/17	1/11	1/9	1/8
2.0	33	1/14	1/9	1/8	1/6

Procedural Sedation

Step 1: Bolus (1.0–2.0mg/kg) 80–160mg ketamine IV/IO over 60 seconds (250–400mg IM if necessary).
Step 2: Consider adding (start low, give more):
- 25–100µg fentanyl IV/IO
- 1–4mg midazolam IV/IO

Step 3: May need to repeat doses as below if procedure lasts longer than 10–15 minutes.
- Ketamine every 10–15 minutes
- Fentanyl every 15–30 minutes
- Midazolam every 30–60 minutes

*dial flow adaptor not accurate for rate < 10mL/h; use drip count

APPENDIX C: COMMON IV MEDS CHEAT SHEET

Common IV Meds Cheat Sheet			
	Moderate Pain	**Pain Dose Range**	**Sedation**
Ketamine	20mg IV	0.1–0.2mg/kg IV	1mg/kg IV
Midazolam	1mg IV	0.5–2mg IV	1mg every 1–6 hours
Morphine	5mg IV	2.5–10mg IV	
Fentanyl IV	25µg IV	25–100µg IV	
Hydromorphone	0.5–1mg IV	0.25–2mg IV	
OTFC	800µg pop: between cheek and gum		
Opioid overdose	Naloxone: Dilute 0.4mg (1mL) with 9mL normal saline. Give 1ml slowly. Repeat dose PRN		
Benzodiazepine overdose	Flumazenil: ▪ Draw 1mL (0.5mg) ▪ Dilute with 4mL sterile water (0.1mg/mL) ▪ Give 3mL/0.3mg over 15 seconds ▪ Additional 1mL/0.1mg every 1 minute PRN Maximum dose, 1mg/h (can cause seizures)		
The moderate-pain category follows this clinical practice guideline philosophy: Prolonged field care analgesia/sedation should begin with smaller amounts of a drug first: START LOW, GO SLOW. The doses are not all inclusive; therefore, the dose by weight or a safe range is also included.			

IV, intravenous; OTFC, oral transmucosal fentanyl citrate; PRN, as needed.

APPENDIX D: RECOMMENDED PAIN AND SEDATION MEDICATION

Recommended Pain and Sedation Medication			
Name	**Purpose/Dose**	**Side Effects and Notes**	**Pharmacology**
Ketamine (Ketalar)	**Background pain:** • Use low dose 10–20mg (0.1–0.2mg/kg) OV/IO PRN. • Avoid oversedation **Breakthrough pain** in hemodynamically stable or unstable patient: IV/IO push: dose every 5 minutes until goal achieved or nystagmus occurs or RR < 10/min. • 10–20mg (or 0.1–0.2mg/kg) slow push **IM/IN**: every 15 minutes until goal achieved or nystagmus occurs • 40–60mg (or 0.5–0.75mg/kg) **Sedation**: IM sedation dose: • 250–400mg (or 4–5mg/kg) **IV/IO sedation** loading dose: • 1mg/kg IV push over 60 seconds Then **IV/IO drip** for ongoing sedation (load above dose, then drip): • Nonintubated: 1mg/kg/h • Intubated 1–2mg/kg/h	• Cataleptic-like state (dissociated from the surrounding environment) • Respiratory depression at higher doses (>1mg/kg), especially with fast administration IV/IO • Sialorrhea (hypersalivation) (can be problematic in an austere setting). • Releases endogenous catecholamines (epinephrine, norepinephrine), which maintain (or increase) blood pressure and heart rate. • *Consider adding midazolam to avoid emergence phenomenon (e.g., delusions, agitation, irrational/violent behavior) in adults with higher doses (>0.3mg/kg IV/IO)* • *Consider glycopyrrolate if significant sialorrhea* • *Consider antiemetic (e.g., odansatron) empirically (may vomit when recovering from sedation)* • *To avoid rapid respiratory depression, IV/IO administration should be slow: Push no faster than over 60 seconds* • No additional sedation or analgesic effects with doses >1.5mg/kg—only longer duration of effects. • There are no absolute contraindications for the use of ketamine; ketamine is safe for use in TBI and/or eye injury.	• NMDA antagonist • Time to onset: 30 seconds IV or 1–5 minutes IM • Duration of action: 10–15 minutes IV or 20–30 • minutes IM • S(+) ketamine has four times the affinity of R(−) ketamine for the NMDA receptor (S ketamine is common in non-US pharmacies) • In practice, S(+) ketamine (e.g., Esketamin, Ketanest) is twice as potent; use half the recommended dose in mg as racemic (“regular”) ketamine • Mid-range dose (0.3–0.8mg/kg IV/IO) has the highest incidence of emergence reactions and dysphoria. AVOID THIS DOSE WHENEVER POSSIBLE. Treat with midazolam or other benzodiazepine (or rebolus ketamine with sedation dose) • Metabolized in the liver to an active metabolite, norketamine, which has a potency one-third that of ketamine • Renal excretion
Hydromorphone (Dilaudid)*	Breakthrough pain in hemodynamically stable patient: IV/IO/ IN: dose every 5 minutes until goal achieved or RR < 10/min. • Nonintubated: 0.25–2mg • Intubated: 1–4mg IM: not recommended	• Respiratory/cardiac/mental status depression • Nausea/vomiting • Pruritus (itching) • Constipation	• Onset <5 minutes • Duration of action 1–4 hours • Hepatic metabolism • Renal clearance (~10% as unchanged drug) • Caution in hepatic/renal impairment (reduce dose by 25%) • IM dose variable and delayed

Recommended Pain and Sedation Medication			
Name	**Purpose/Dose**	**Side Effects and Notes**	**Pharmacology**

Fentanyl* (Actiq)**	**Background pain:**
	Oral: only in NONINTUBATED, awake patients, per TCCC guidelines
	• OTFC 800µg
	  • Place lozenge between the cheek and the gum
	  • Do not chew the lozenge
	Breakthrough pain in hemodynamically stable patient:
	IV/IO/ IN: dose every 5 minutes until goal achieved or RR < 10/min.
	• Nonintubated: 25–50µg
	• Intubated: 50–200µg
	**IV push should be over 30–60 seconds, monitor for difficulty breathing (e.g., rigid chest syndrome)
	IM: not recommended
		• Respiratory/cardiac/mental status depression
		• Nausea/vomiting
		• Pruritus (itching)
		• Constipation
		
		Unique concerns:
		• Chest-wall muscle rigidity with rapid IV infusion (rare)
		• Bradycardia (rare)
		• QT-interval prolongation (rare)
		• Highly lipophilic
			• Rapid IV onset (<2 minutes)
			• Duration of action: 30–60 minutes
			• Hepatic metabolism
			• Renal clearance (~10% as unchanged drug)
			• Caution in hepatic/renal impairment (reduce dose by 25%)

Morphine**	**Breakthrough pain** in hemodynamically stable patient: IV/IO/ IN: dose every 5 minutes until goal achieved or RR < 10/min. • Nonintubated: 2.5–10mg • Intubated: 5–10mg IM: not preferred; can give 5–10mg IM if necessary	• Respiratory/cardiac/mental status depression • Nausea/vomiting • Pruritus (itching) • Constipation • Anticholinergic like effects, particularly urinary retention	• Onset <5 minutes. • Active metabolites. • **Duration of action: 1–4 hours** • 85% renal clearance; 7%–10% bile/stool clearance • Significantly reduced clearance in renal failure • IM dose variable and delayed
Percocet	**Background pain** Contains oxycodone (5mg) AND acetaminophen (325mg) **PO/enteral (may be crushed):** 1–2 tabs every 4–6 hours. • DO NOT exceed 4,000mg total acetaminophen per day.	• Respiratory/cardiac/mental status depression • Nausea/vomiting • Pruritus (itching) • Constipation • Hypersensitivity (rare) • Liver toxicity (acetaminophen) at high doses or if compromised liver function at baseline	• Oxycodone • Hepatic metabolism • Active metabolites • Urinary excretion • **Duration of effect: 4–6 hours** Acetaminophen (see below)
Midazolam (Versed)	**Sedation** (includes anxiety or agitation): **IV/IO**: dose every 5 minutes until goal achieved or RR < 10/min. • Nonintubated: 0.5–2mg • Intubated: 1–4mg **IM**: not recommended	• Respiratory/cardiac/mental status depression • Amnestic • Nausea/vomiting • Hypotension • Constipation • Personnel and equipment needed for standard respiratory resuscitation should be available during midazolam administration.	• Onset: 1–5 minutes • **Duration of effect: 1–4 hours** • Hepatic metabolism (active metabolites) • Renal excretion
Glycopyrrolate (Robinul)	Antisialogogue (i.e., to stop hypersalivation from ketamine) **SC/IM/IV/IO**: • 0.1–0.2mg every 4 hours	• Tachycardia/palpitations • Nausea/vomiting • Flushing • Urinary retention • Not to exceed 4 doses/d	• Anticholinergic • Rapid onset • Duration of effect: 2–6 hours • Renal excretion (85%, 80% unchanged)

Recommended Pain and Sedation Medication			
Name	**Purpose/Dose**	**Side Effects and Notes**	**Pharmacology**
Acetaminophen (Tylenol)	For mild to moderate pain: **IV/PO**: 500–1000mg every 6 hours	• Hypersensitivity (rare) • Increased serum transaminases • Nausea/vomiting (IV) • **Acute liver failure: limit daily dose of acetaminophen and acetaminophen-containing products (e.g., Percocet) to 4,000mg**	• Onset: <1 hour PO, 5–10 minutes IV • Duration of effect: 4–6 hours • Hepatic metabolism • Renal excretion
Odansatron (Zofran)	For nausea and vomiting: • 4mg ODT/IV/IO/IM, every 4–8 hours PRN • Can repeat once at 15 minutes if nausea and vomiting are not improved	• Maximum 8mg in any 8-hour interval • QT-interval prolongation (rare) • Constipation • Dizziness/headache	• Selective serotonin 5-HT3 receptor antagonist • Hepatic metabolism • Excreted in the urine and feces
Flumazenil (Romazicon)	For reversal of benzodiazepine overdose (e.g., midazolam) • 0.2mg IV over 15 seconds	• DO NOT USE IN CHRONIC BENZODIAZEPINE USERS! (May cause seizures) • Use only to reverse benzodiazepines YOU have given the patient.	• Specific benzodiazepine receptor antagonist • **Resedation may occur 20–60 minutes after initial dose, may require redosing** • Hepatic metabolism • Renal excretion
Naloxone (Narcan)	For reversal of opioid overdose • 0.4–2mg IV/IM/SC/IN; repeat every 2–3 minutes PRN; not to exceed 10mg (0.01mg/kg)	• Withdrawal reaction precipitated • Abrupt reversal of opioid depression may result in nausea, vomiting, sweating, tachycardia, increased blood pressure, and tremulousness • **Short duration of action relative to longer-acting opioids (e.g., morphine); may need to redose before opioid effect has worn off**	• Competitive opioid antagonist • Onset: 2 minutes IV; 2–5 minutes IM/SC • **Duration of effect: 30–60 minutes, may require redosing** • Hepatic metabolism • Renal excretion
Diphenhydramine (Benadryl)	For itching or allergic reaction (may also cause drowsiness) • 25–50mg IV/IO/PO every 4–6 hours PRN (maximum: 400mg daily)	• May potentiate the effect of other sedative agents • May reduce seizure threshold • May cause paradoxical CNS stimulation (e.g., agitation or anxiety) and/or psychosis • Mild anticholinergic and may cause dry secretions (dry mouth, constipation, urinary retention), blurred vision, flushing, fever, tachycardia • May reduce nausea	• Histamine receptor (H1) antagonist • Hepatic metabolism • Renal excretion

CNS, central nervous system; IM, intramuscular; IN, intranasal; IO, interosseous; IV, intravenous; NMDA, N-methyl-d-aspartate; ODT, oral disintegrating tablet; OTFC, oral transmucosal fentanyl citrate; PO, *per os* (by mouth); PRN, as needed; RR, respiratory rate; SC, subcutaneous; TBI, traumatic brain injury; TCCC, Tactical Combat Casualty Care.

***Hydromorphone is selected as the opioid medication of choice in the PFC setting for the following reasons:**

1. Long acting
2. Lower likelihood of accumulating in the setting of organ dysfunction (particularly renal injury/insufficiency) and, therefore, less likely to cause respiratory depression or hypotension
3. Smaller doses produce greater effect; thus, less medication needs to be carried for longer duration of treatment
4. Less histamine activation, less pruritus, better tolerated

****Morphine**

1. Long acting
2. Can give IM if necessary, but not preferred
3. More side-effects compared with hydromorphone (e.g., higher rate of respiratory depression, hypotension, and pruritus)

*****Fentanyl**

1. Short acting
2. Faster onset
3. Greatest risk of respiratory depression; highly recommend monitoring SpO2 (oxygen saturation)
4. Be prepared to support breathing if necessary
5. Reserved for severe pain or procedures

APPENDIX E: REGIONAL ANESTHESIA – RECOMMENDATIONS

REGIONAL ANESTHESIA - RECOMMENDATIONS

WORKING DEFINITION

It is a useful technique of local anesthetic agent injection adjacent to a single nerve or a nerve bundle, that can markedly reduce or eliminate limb-related pain without negative systemic effects such as respiratory depression, sedation or hypotension.

BEFORE ATTEMPTING - COMPETENCY IN ANY BLOCK PERFORMED MUST BE DOCUMENTED
ULTRASOUND GUIDANCE IS THE PREFERRED MODALITY FOR BLOCKS

BENEFITS

- Superior pain control in patients with limb injuries.
- Successful block decreases your patient's need for systemic analgesia. May need less or none at all.
- It is logistically easier to take care of a patients who doesn't need heavy sedation or systemic analgesia.

RISK

- LAST (local anesthetic systemic toxicity) - serious cardiovascular & CNS toxicity from accidental injection into the blood vessels or from absorption into systemic circulation - know signs & symptoms; stay out of blood vessels when injecting local anesthetics!
- Accidental nerve damage from needle or injection into the nerve - don't inject against resistance!
- Increased risk of unrecognized compartment syndrome or local pressure wounds given patient cannot provide feedback due to lack of sensory (+/- motor) function in a blocked extremity.
- Risk from injury to surrounding structures such as blood vessel injury or a pneumothorax.

SYMPTOMS & SIGNS OF LAST:

- NERVOUS SYSTEM:
  - perioral numbness, tingling, metallic taste, tinnitus, muscle twitching, visual disturbance, extreme anxiety, screaming, impending death feeling, SEIZURE, COMA
- CARDIOVASCULAR SYSTEM:
  - chest pain, shortness of breath, diaphoresis, ARRHYTHMIA, HYPOTENSION, CARDIOVASCULAR COLLAPSE

RECOMMENDED MODALITIES:

- ☐ **Ultrasound-guidance** for real-time visualization of targeted nerves, needle & anesthetic spread. It is recommended for any block performed (except digital blocks).
- ☐ **Paresthesia/anatomical technique** may be used for distal nerve blocks if no ultrasound available.

HOW TO MINIMIZE RISK:

- ☐ Know the drugs you have available and ensure you have easy access to procedural references prior to deployment.
- ☐ Establish **baseline neurological function** of a given extremity prior to block.
- ☐ **Calculate the maximum total dose** of local anesthetic for your patient and never exceed it when performing multiple blocks.
- ☐ Use **local anesthetics with epinephrine for all blocks** to facilitate immediate recognition of intravascular injection.
- ☐ Use **blunt-tip needles** to minimize nerve injury.
- ☐ **Monitor your patient** during the injection & for 15-20 minutes after the procedure.
- ☐ Use **pulse oximetry with audible signal** as the **minimum** monitoring device when performing regional nerve blocks.
- ☐ **Mark & date all the block sites** with a permanent marker on the skin.
- ☐ **Pad** all the pressure points
- ☐ Know how to manage **LAST** syndrome (see checklist).

RECOMMENDED LOCAL ANESTHETIC

ROPIVACAINE (0.2 % - 2mg/mL or 0.5% - 5mg/mL) is the local anesthetic of choice due to its excellent efficacy and improved cardiovascular safety profile.

MAXIMUM CUMULATIVE DOSE: 3 mg/kg (all blocks at multiple sites combined)

- ☐ 0.2% solution: 1.5mL/kg
- ☐ 0.5% solution: 0.6mL/kg

ONSET & DURATION: approximately 20 minutes from injection to onset of block. An effective dose provides 4-8 hours of anesthesia. The analgesic effect lasts for 5-12 hours.

Regional Anesthesia – Recommendations (Continued)

REGIONAL ANESTHESIA - WORKSHEET

PATIENT'S WEIGHT [kg]:	MAXIMUM CUMULATIVE DOSE:

RECOMMENDED UPPER EXTREMITY BLOCKS:

SEE REGIONAL ANESTHESIA REFERENCE - ULTRASOUND-GUIDED NERVE BLOCKS

- ☐ **SUPRACLAVICULAR BRACHIAL PLEXUS BLOCK** (must be performed under ultrasound guidance; inject 20-25mL of local anesthetic)
- ☐ **AXILLARY BRACHIAL PLEXUS BLOCK** (preferably under ultrasound guidance; inject 15-20mL of local anesthetic)
- ☐ **WRIST BLOCK: radial, median & ulnar nerves** (ultrasound use is optional; inject a total of 10mL of local anesthetic for all 3 nerves)
- ☐ **DIGITAL BLOCK** (inject < 5mL of local anesthetic)

RECOMMENDED LOWER EXTREMITY BLOCKS:

SEE REGIONAL ANESTHESIA (3) ULTRASOUND-GUIDED NERVE BLOCKS REFERENCE

- ☐ **FEMORAL NERVE BLOCK** (use ultrasound guidance; inject 10-20mL of local anesthetic)
- ☐ **PROXIMAL SCIATIC NERVE BLOCK** (subgluteal approach; use ultrasound guidance; inject 15-20mL of local anesthetic)
- ☐ **DISTAL SCIATIC NERVE BLOCK** (popliteal approach; use ultrasound guidance; inject 20mL of local anesthetic)
- ☐ **SAPHENOUS BLOCK** (ultrasound use is optional: proximal approach at tibial tuberosity; inject 10mL of local anesthetic)
- ☐ **ANKLE BLOCK: saphenous, sural, posterior tibial, superficial & deep peroneal nerves;** ultrasound use is optional; inject a total of 20mL of local anesthetic for all 5 nerves)
- ☐ **DIGITAL BLOCK** (inject < 5mL of local anesthetic)

CONTRAINDICATIONS:

- UNTRAINED PROVIDER
- Refusal & **inability to communicate with patient**
- Infants, children, elderly
- Infection at the injection site
- Trauma or history of trauma at the injection site
- Systemic anticoagulation/coagulopathy
- Pre-existing neurological disease

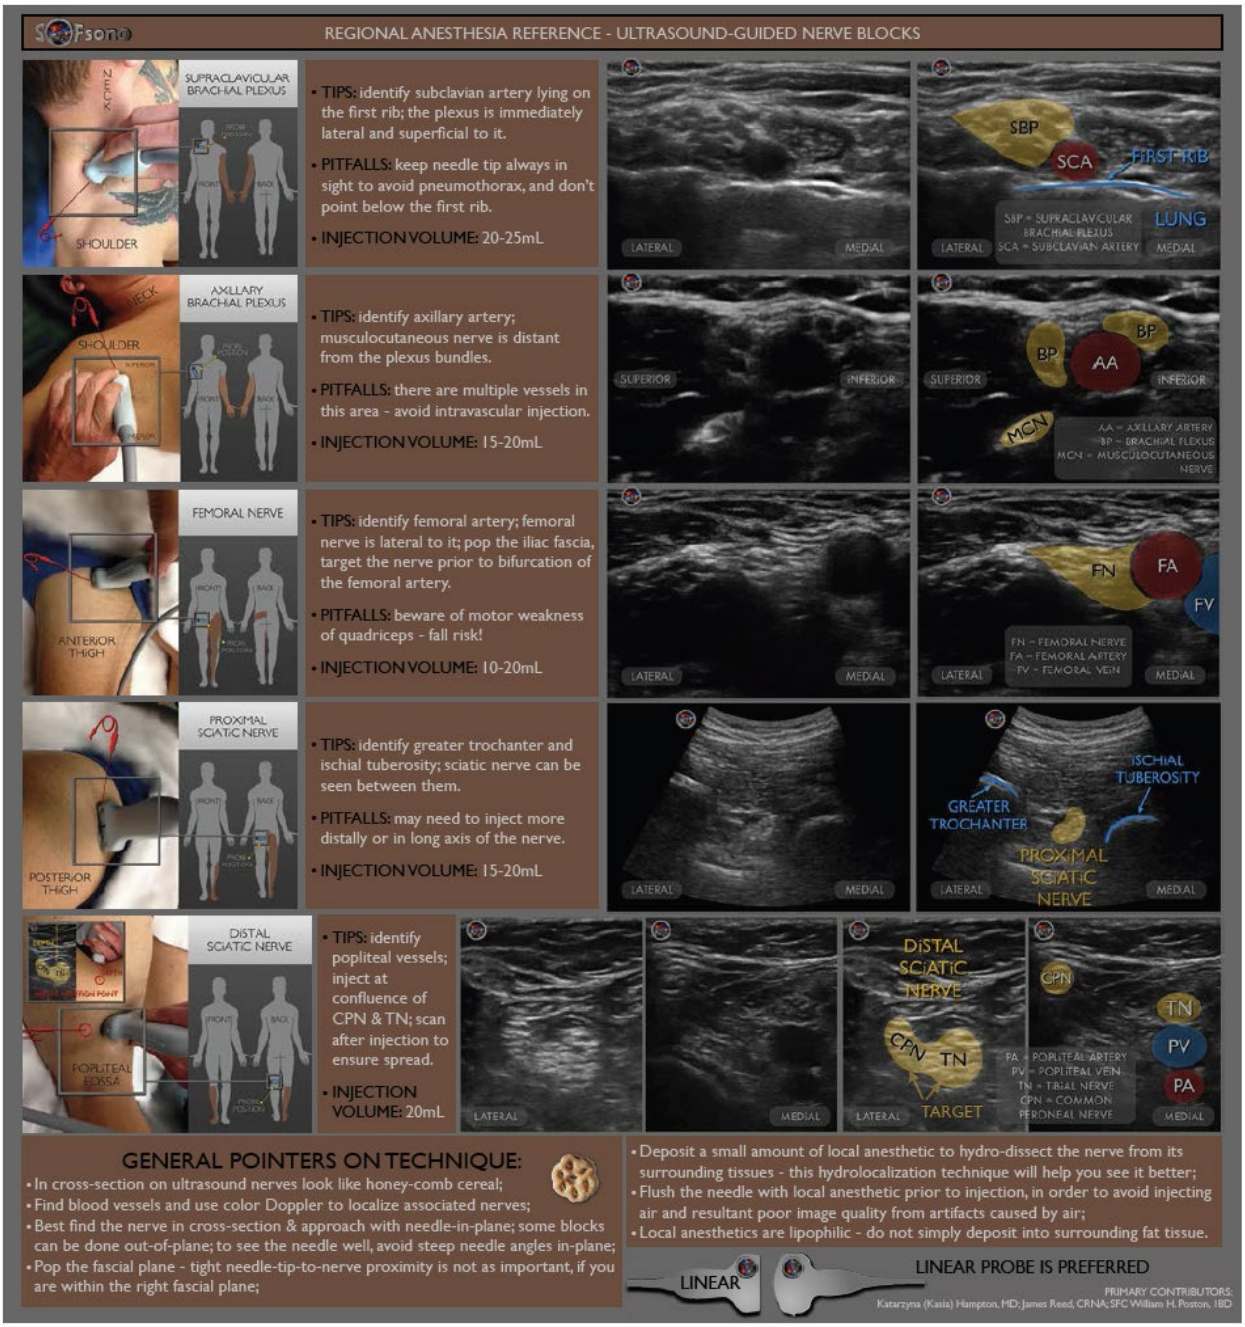
TECHNIQUE:

- Identify target nerve according to training
- Gather equipment and place the patient on monitor:
  - ☐ MINIMUM: pulse oximetry with audible signal
  - ☐ BETTER: add blood pressure monitoring
  - ☐ BEST: full monitor with EKG leads
- Prepare & label the syringes with local ANESTHETIC
- Clean (preferably sterile) procedure: cleanse injection site with chlorhexidine (preferred), betadine or alcohol, & use gloves (best sterile)
- Ensure good verbal and visual communication with the patient prior to injection
- Introduce needle and aspirate for blood; then inject 1 mL of anesthetic, and if no resistance, then aspirate again & slowly inject 3-5mL, and wait 60 seconds to monitor for toxicity. **STOP IF if any signs or symptoms of toxicity or other adverse events occur**
- Continue injection if no changes occur
- **Always aspirate before any injection**
- Slowly inject your target dose for a given block in **5-mL increments** given over 10-15 sec each, and **always aspirate for blood** between each 5-mL increment
- Mark and date each block site

Local Anesthetic Systemic Toxicity (LAST) checklist:

- STOP injection at first sign or symptom!
- Airway management: use 100% oxygen
- Seizure management: benzodiazepines are preferred; can give propofol (25-50mg) if hemodynamically stable
- Use ACLS protocols for cardiovascular collapse
- **20% LIPID EMULSION** is the antidote:
  - ☐ 1 mL/kg every 3-5 minutes IV, up to 3mL/kg IV during ACLS
  - ☐ Follow with continuous infusion 0.25mL/kg/min
  - ☐ Double the infusion rate to 0.5mL/kg/min if blood pressure remains low
  - ☐ Continue infusion for at least 10 minutes once hemodynamically stable
  - ☐ Upper limit: approx. 10mL/kg IV over 30 minutes

Regional Anesthesia – Recommendations (Continued)



REGIONAL ANESTHESIA REFERENCE - ULTRASOUND-GUIDED NERVE BLOCKS
SUPRACLAVICULAR BRACHIAL PLEXUS
SHOULDER
• TIPS: identify subclavian artery lying on the first rib; the plexus is immediately lateral and superficial to it.
• PITFALLS: keep needle tip always in sight to avoid pneumothorax, and don't point below the first rib.
• INJECTION VOLUME: 20-25mL
LATERAL
MEDIAL
SBP
SCA
FIRST RIB
LUNG
SBP = SUPRACLAVICULAR BRACHIAL PLEXUS
SCA = SUBCLAVIAN ARTERY
AXILLARY BRACHIAL PLEXUS
NECK
SHOULDER
• TIPS: identify axillary artery; musculocutaneous nerve is distant from the plexus bundles.
• PITFALLS: there are multiple vessels in this area - avoid intravascular injection.
• INJECTION VOLUME: 15-20mL
SUPERIOR
INFERIOR
BP
AA
MCN
AA = AXILLARY ARTERY
BP = BRACHIAL PLEXUS
MCN = MUSCULOCUTANEOUS NERVE
FEMORAL NERVE
ANTERIOR THIGH
• TIPS: identify femoral artery; femoral nerve is lateral to it; pop the iliac fascia, target the nerve prior to bifurcation of the femoral artery.
• PITFALLS: beware of motor weakness of quadriceps - fall risk!
• INJECTION VOLUME: 10-20mL
FN
FA
FV
FN = FEMORAL NERVE
FA = FEMORAL ARTERY
FV = FEMORAL VEIN
PROXIMAL SCIATIC NERVE
POSTERIOR THIGH
• TIPS: identify greater trochanter and ischial tuberosity; sciatic nerve can be seen between them.
• PITFALLS: may need to inject more distally or in long axis of the nerve.
• INJECTION VOLUME: 15-20mL

PV
PA
PA = POPLITEAL ARTERY
PV = POPLITEAL VEIN
TN = TIBIAL NERVE
CPN = COMMON PERONEAL NERVE
GENERAL POINTERS ON TECHNIQUE:
• In cross-section on ultrasound nerves look like honey-comb cereal;
• Find blood vessels and use color Doppler to localize associated nerves;
• Best find the nerve in cross-section & approach with needle-in-plane; some blocks can be done out-of-plane; to see the needle well, avoid steep needle angles in-plane;
• Pop the fascial plane - tight needle-tip-to-nerve proximity is not as important, if you are within the right fascial plane;
• Deposit a small amount of local anesthetic to hydro-dissect the nerve from its surrounding tissues - this hydrolocalization technique will help you see it better;
• Flush the needle with local anesthetic prior to injection, in order to avoid injecting air and resultant poor image quality from artifacts caused by air;
• Local anesthetics are lipophilic - do not simply deposit into surrounding fat tissue.

APPENDIX F: THE RICHMOND AGITATION-SEDATION SCALE (RASS)[12]

+4	Combative	Combative, violent, immediate danger to staff
+3	Very agitated	Pulls to remove tubes or catheters; aggressive
+2	Agitated	Frequent non purposeful movement; fights ventilator
+1	Restless	Anxious, apprehensive, movements not aggressive
0	Alert and calm	Spontaneously pays attention to caregiver
-1	Drowsy	Not fully alert but has sustained awakening to voice (eye opening and contact >10 seconds)
-2	Light sedation	Briefly awakens to voice (eyes open and contact <10 seconds)
-3	Moderate sedation	Movement of eye opening to voice (no eye contact)
-4	Deep sedation	No response to voice but movement or eye opening to physical stimulation
-5	Unarousable	No response to voice or physical stimulation

Procedure for RASS assessment	Score
1. Observe patient. • Patient is alert, restless, or agitated.	0 to +4
2. If not alert, state patient's name and tell patient to open eyes and look at speaker. • Patient awakens with sustained eye opening and eye contact. • Patient awakens with eye opening and eye contact, but not sustained. • Patient has any movement in response to voice but no eye contact.	 −1 −2 –3
3. When no response to verbal stimulation, physically stimulate patient by shaking shoulder and/or rubbing sternum. • Patient has any movement to physical stimulation. • Patient has no response to any stimulation.	 −4 −5

APPENDIX G: PLANNING CONSIDERATIONS

Best:	Better:	Minimum:
• Fluids: fluid for medication administration/drip (normal saline [NS]: 100mL/250mL bags and 5mL/10mL prefilled syringes) • Equipment: portable monitor with capnography, laboratory capability for serum electrolytes, arterial blood gases, lactate, Foley catheter with graduated collection system, portable ventilator, portable suction, portable sonography, airway management kit to include endotracheal suction catheter • Macro/microdrip intravenous (IV) administration tubing; • infusion pump • Analgesic medications: Ketamine, hydromorphone, fentanyl, morphine (for IV use), oral transmucosal fentanyl citrate (OTFC), Percocet tabs for oral (PO) use • Mild pain: meloxicam, acetaminophen • Sedation/Anxiety: midazolam for IV use (diazepam tabs for PO) • Mild pain: meloxicam, acetaminophen • Antisialogogue: glycopyrrolate • Antiemetic: ondansatron • Antihistamine and reversals: diyphenhydramine, flumazenil, naloxone • Local/regional anesthesia: 2% lidocaine/ropivacaine • Monitoring: portable monitor providing continuous vital sign display; capnography if intubated; document vital signs trends, intake and output, GCS, and pain level every 5 minutes until goal achieved, every 15 minutes thereafter; pain assessment sheet • Communications: real-time video telemedicine consultation • Push-pack capability: prepackaged additional 24-hour supplies of fluids, and medications for scenarios >24 hours.	• Fluid for medication administration/ drip (NS: 250mL bags and 10mL prefilled syringes) • Equipment: blood pressure cuff, stethoscope, pulse oximeter, capnometer, portable ventilator, Stimuplex (peripheral nerve stimulation), airway management kit to include endotracheal suction catheter, Micro/macrodrip tubing with dial-a-flow adaptor • Graduated container to monitor urine output • Analgesic medications: ketamine, hydromorphone for IV • Percocet tabs for PO • Mild pain: meloxicam, acetaminophen • Sedation/Anxiety: midazolam • Antiemetic: ondansatron • Antihistamine and reversals: diyphenhydramine, flumazenil, naloxone • Nonsteroidal anti-inflammatory drug (NSAID): acetminophen • Local/regional anesthesia: 2% lidocaine/ropivacaine • Monitoring: frequent vital signs, examination, fluid input/urine output • Communications: telephone; e-mail digital photos	• Fluids: NS: 250mL bags • Equipment: blood pressure cuff, stethoscope, pulse oximeter, bag-valve mask with positive end-expiratory pressure valve, airway management kit • Macrodrip tubing and counting drops per second to get infusion rate • Analgesic medications: ketamine, hydromorphone for IV, Percocet tabs for PO • Mild pain: meloxicam, acetaminophen • Sedation/Anxiety: midazolam • Antiemetic: ondansatron • Antihistamine and reversals: diyphenhydramine, flumazenil, naloxone • Local/regional anesthesia: 2% lidocaine/ropivacaine • Monitoring: frequent vital signs, examination, fluid input documented on preprinted or improvised flowsheet. • Communications: telephone

.

APPENDIX H: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Anesthesia for Trauma Patients

Guidelines incorporate the induction and maintenance of anesthesia into an ongoing resuscitation during surgery for a trauma patient in extremis.

SUMMARY OF CHANGES

01 Sep 2023 update: DEVICE data regarding video laryngoscope.

June 2023 update

- Calcium administration changed to 1 gram calcium
- Tranexamic acid (TXA) 2gm bolus is now favored over the traditional 1gm prehospital bolus followed by 1gm infusion over 8 hours. The 2gm TXA bolus should be given as close to the time of injury as possible and not outside of the 3 hours window.

05 Apr 2021 updates

1. Use Whole Blood (WB) if available. FDA-approved cold stored WB is preferred over fresh WB (non-FDA approved).
2. Initiate infusion of 2gmTranexamic Acid (TXA) IV/IO ASAP or within 3 hours of injury.
3. Carefully follow calcium concentration during massive transfusion. Consider giving empiric calcium if hypotensive.
4. Stronger evidence exists for use of vasopressin in hemorrhagic shock. Consider vasopressin bolus of 2-4 units followed by a vasopressin infusion (0.04 U/min) in cases of refractory shock.

BACKGROUND

Resuscitation goals for trauma patients have undergone significant change in the past decade. Appropriate blood product transfusion ratios, use of pharmacologic adjuncts (e.g., TXA) and other modalities have improved survival for the wounded combatant. In the operating room (OR), resuscitation occurs in the context of providing an anesthetic which minimizes hemodynamic instability in the severely injured patient. It is imperative, therefore, that the management of this resuscitation occurs simultaneously with surgery and anesthesia. While recent review articles, checklists and textbooks have drawn attention to the role of anesthetic resuscitation concurrent with surgical correction of injury, there is no guideline for the induction, maintenance, and transfer of anesthetic care of the military trauma patient in extremis.[1-4]

SPECIFIC CONSIDERATIONS FOR TRAUMA ANESTHESIA

PRE-INDUCTION

- Hypothermia is one of the arms of the lethal triad of coagulopathy, acidosis, and hypothermia.[5] As such, it is important to warm the OR to greater than 30C and have a warmed intravenous (IV) line, forced air warmer, and rapid infuser with warming capability immediately available. Standard checks (e.g., anesthesia machine check, airway equipment is in proper working order) assure that vital equipment is ready for immediate use.
- Establishment of a massive transfusion protocol and effective communication with the blood bank is essential and can improve survival.[6] The *Damage Control Resuscitation CPG*[7] defines the massive transfusion protocol for the combat theater. At all roles of care, awareness of the individual military medical facilities (MTFs) on-hand resources (including walking blood bank) and applicable protocols are key considerations.
- The presence of anesthesia in the trauma bay is necessary for smooth transition of care to the OR and offers the opportunity to assist with invasive procedures. Identification of team roles prior to patient arrival facilitates effective transfer from the delivering team.

INDUCTION OF ANESTHESIA

1. Induction of anesthesia in the exsanguinating patient can be challenging. **Ongoing volume resuscitation to prevent occurrence of cardiac arrest** in the peri-anesthetic period is critical.

2. After a patient is identified for surgery, **verification of functioning vascular access** (either intravenous or intraosseous) and placement of monitoring devices (e.g., oxygen saturation, blood pressure, and electrocardiogram) must occur quickly.

3. **Do not delay induction of the patient in extremis in order to place the central venous access or invasive monitoring.** Placing monitors at the same time as the surgical prep and drape can save time in a crisis. A wide draping procedure with “arms out” ensures adequate surgical exposure, while affording access to the arms as needed after the start of surgery. Pre-oxygenation with four full vital capacity breaths can “de-nitrogenate” the end alveoli sufficiently to optimize oxygenation prior to rapid sequence induction. In the obtunded patient, it may not be possible to achieve four vital capacity breaths prior to induction, and one must proceed with induction relying upon apneic oxygenation.

4. There are a variety of **sedative hypnotics** available for induction of anesthesia. Standard induction dosages should be reduced and titrated to balance the induction of anesthesia with hemodynamic changes. Ketamine (1 mg/kg) will not decrease the systemic vascular resistance to the same extent as other sedative hypnotics. While Propofol is a standard induction agent, it can decrease the systemic vascular resistance

significantly. It is prudent to use reduced doses of Propofol (0.5-1 mg/kg) in hypotensive patients. Ongoing volume resuscitation is vital to prevent vascular collapse.

5. **Neuromuscular relaxation** sufficient to facilitate endotracheal intubation can be achieved in approximately 45 seconds with succinylcholine in a standard rapid sequence induction dose (1mg/kg). Rocuronium is a non-depolarizing neuromuscular relaxant useful in cases where succinylcholine may be contraindicated (e.g., burns, spinal cord injury, hyperkalemia). An increased dose of Rocuronium (1-1.2 mg/kg) can produce intubating conditions similar to succinylcholine in approximately 60 seconds.

6. **Prompt endotracheal intubation of the trachea following induction** mitigates the risk of aspiration. Rapid sequence induction (RSI) with direct laryngoscopy is a safe and effective method to secure the airway of the trauma patient.[8, 9] The efficacy of in-line stabilization during RSI is somewhat controversial; however, it remains prudent to minimize the manipulation of the cervical spine to the extent possible during laryngoscopy. Regardless, it is re-assuring to know that spinal cord injury following direct laryngoscopy rarely causes or worsens cervical spine injury.[10]

7. A variety of **airway adjuncts** are available to the laryngoscopist. The gum elastic bougie can be helpful in securing a challenging airway and is a low-cost, effective airway adjunct.[11] Video laryngoscopy can provide an improved view of the vocal cords during intubation and has recently been shown to improve first pass success rate, especially for less experienced providers. Therefore, video laryngoscopes are preferred over direct laryngoscopes when available.[12] It remains prudent to have a limited number of immediately available airway adjuncts with which one is familiar, rather than a larger selection of less familiar equipment.[13] An alternate plan, including equipment for surgical airway management, must also be immediately available. (See *Airway Management of Traumatic Injuries CPG*[14])

8. After intubation of the trachea and verification of end tidal carbon dioxide, communication with the surgeon ensures that the operation proceeds in a timely fashion. **Placement of an orogastric tube** at this point may potentially decrease the risk of aspiration.

MAINTENANCE OF ANESTHESIA

- **Maintenance of anesthesia can be accomplished via an inhalational volatile agent or via a total intravenous anesthetic (TIVA).**[15] Both approaches must be carefully titrated to the hemodynamic profile while assuring adequate sedation/hypnosis and analgesia. Awareness during anesthesia and the acute pain response can be mitigated during TIVA by assuring that both a sedative hypnotic (e.g., Propofol, benzodiazepine) and an analgesic (e.g., narcotic) are being administered. Narcotic dose can be titrated to hemodynamics.
- **Adequate IV access** must be assured immediately (e.g., large bore peripheral IV, intraosseous, rapid infusion catheter (RIC), Cordis central line). Placement of additional IV access or an arterial line (if indicated for continuous monitoring of beat-to-beat blood pressure) can be undertaken without delaying the start of the operation.
- Sending **a baseline set of labs**, to include coagulation studies and base excess, at the start of the case can set a reference point for the remainder of the resuscitation. Consider validation of Point of Care (POC) testing (e.g., iSTAT values) with traditional laboratory assays. Ensure all laboratory equipment and POC equipment are maintained within the manufacturer's biomedical engineering standards.
- The maintenance of anesthesia and the resuscitation can be guided by following the trend in **mean arterial pressure (MAP).** While the ideal blood pressure is controversial, a MAP < 55 mmHg has been associated with acute kidney injury and myocardial injury during anesthetics for non-cardiac surgery.[16] Maintaining a MAP > 60 mmHg will facilitate end organ perfusion without exacerbating any unsecured bleeding.

- **Traumatic brain injury (TBI)** represents a unique situation in which isolated episodes of hypotension can worsen mortality.[17] It is, therefore, advisable to maintain systolic blood pressure > 110 mmHg in patients with documented or suspected TBI. (See *Neurosurgery and Severe Head Injury CPG*[18])

RESUSCITATION

NOTE: *See Damage Control Resuscitation CPG*[7]

- **Ratios of fresh frozen plasma (FFP): packed red blood cells (PRBC)** approaching 1:1 have been demonstrated to confer a survival benefit in military and civilian trauma patients.[19, 20] While the ideal ratio of FFP: PRBC remains somewhat controversial, it is fair to say early administration of plasma and platelets is appropriate for the trauma patient in extremis.[21] When available, use cold stored whole blood. Fresh whole blood may also be safely used. A more exhaustive discussion of damage control resuscitation is found elsewhere in the CPGs and is recommended reading for this subject. Communication with the surgical team regarding the progress of the resuscitation and the stage of the surgery is an important factor in overall success.

- **TXA** is a potent synthetic lysine derivative that functions as an anti-fibrinolytic. Administration of 2 gm of TXA IV/IO-ASAP or within 3 hours of injury has been demonstrated to improve survival in a highly powered, randomized trial of international trauma patients.[22] A survival advantage was also demonstrated with the use of TXA in military trauma.[23] A recent analysis of prehospital dosing strategies for TXA in moderate to severe TBI found a significantly improved neurologic function at 6 months with a 2 gm bolus given prehospital compared to a 1 gm bolus + 1 gm infusion or placebo for the subset of patients with confirmed intracerebral hemorrhage, and no difference in survival or complications for either dose or placebo for all patients treated based on prehospital Glasgow Coma Scale (GCS) 3-12.[24] In other work, when prehospital TXA was administered within 1 hour of injury to patients in severe shock there was a 30 day mortality benefit.[25] More detailed analysis of timing and dosing regimens is on-going, but in the meantime it is safe to administer an initial 2 gm bolus of TXA

- **Hydrocortisone** is a potent mineralocorticoid which can augment blood pressure during shock states when the hypothalamic–pituitary–adrenal (HPA) axis is suppressed and unable to mount an effective stress response. Administration of hydrocortisone 100 mg can improve vasopressor responsiveness in critically ill trauma patients.[26,27]

- **Hypocalcemia** must be avoided in massive blood transfusion. Hypocalcemia is often due to chelation of calcium by the citrate preservative in stored blood. Trauma patients can be hypocalcemic even prior to blood product administration.[28] Severe hypocalcemia (iCa <0.9), has been associated with higher lactate, lower pH and worsened mortality.[29 30] Administration of 1 gm calcium-can correct this potentially life-threatening hypocalcemia, and the hypotension associated with it. Consider following ionized calcium levels with POC chemistry analysis. If this in unavailable, then consider empiric administration of 1gm calcium after each 4th unit of blood.[31]

- **Use of vasopressors** in trauma is generally associated with higher mortality.[32] In one analysis evaluating trauma patients who received vasopressor support, vasopressin was found to be the only vasopressor in which the 95% confidence interval for mortality crossed unity, suggesting non-significance.[33] Vasopressin was further evaluated by in a randomized controlled trial in which trauma patients received a vasopressin bolus followed by an infusion. The vasopressin group required fewer blood products, had similar mortality and complication rates.[34] In cases of refractory hypotension, a vasopressin bolus (2-4 units) followed by infusion (0.04 U/min) can be given in concert with aggressive blood product administration.

- **Timely administration of antibiotics** can decrease the incidence of post-operative infections and is part of the anesthetic resuscitation. Consider agents that will be effective against skin flora (Gram positive organisms) or, in the event of bowel injury, gastrointestinal flora (anaerobes and Gram negative organisms).

The *Infection Prevention in Combat-Related Injuries CPG* identifies the optimal antibiotics for multiple clinical scenarios.

POST-OPERATIVE/EMERGENCE

- **Low lung volume ventilation** (6mL/kg) can decrease mortality in critically ill patients with the acute respiratory distress syndrome.[35] Even in patients who have not developed the acute respiratory distress syndrome; initiation of low lung volume ventilation can improve outcome. Consider initiation of low lung volume ventilation in the OR.

- **Communication with the next role of care** is vital to maintaining continuity of care. In the deployed setting this may entail a face-to-face conversation with the intensive care unit team, or a report transmitted to a critical care air transport team. (See *Interfacility Transport of Patients between Theater Medical Treatment Facilities CPG)* A detailed written report/anesthetic record documents the operative resuscitation and facilitates transition to the next role of care. Being immediately available in the post-operative period to answer any questions can clarify any issues that may arise.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

1. All trauma patients who undergo surgery within 24 hours of arrival to first surgical role of care (includes all surgeries performed).
2. Patients who receive endotracheal tube/cricothyroidomy/tracheostomy before the initial surgery AND undergo surgical procedure at Role 2 or Role 3.

INTENT (EXPECTED OUTCOMES)

1. Anesthesia care is documented on an anesthetic record and uploaded to Theater Medical Data Story.
2. Trauma patients in the OR maintain a body temperature > 36˚C during surgery.
3. Anesthesia following major trauma will be induced and maintained with less than 20% drop in initial blood pressure.
4. Patients undergoing massive transfusion will receive blood products in 1:1:1:1 ratio (plasma:platelets:RBC: cryoprecipitate).
5. Calcium is administered to patients who have received: one unit and after every 4 units of red blood product transfused.
6. Antibiotics are administered to all patients prior to initiation of surgery incision.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who have anesthesia record received.
2. Number and percentage of trauma patients who maintained a body temperature > 36˚C during surgery (as recorded on anesthesia record).
3. Number and percentage of patients who do not drop systolic blood pressure more than 20 mmHg during the first 15 min after induction of anesthesia.

4. Number and percentage of patients undergoing massive transfusion (>10 u RBC + whole blood with 24 hours after injury) who received blood products in an FFP:RBC ratio between 0.5:1 to 1:1.5 while in the OR (as recorded on anesthesia record).

5. Number and percentage of patients undergoing massive transfusion (>10 u RBC + whole blood with 24 hours after injury) who receive platelet or whole blood transfusion while in the OR (as recorded on anesthesia record).

6. Number and percentage of patients who received more than 1 units of blood products transfused who also received calcium (as recorded on anesthesia record).

7. Number and percentage of patients who received antibiotic before surgery or documented no antibiotic indicated.

DATA SOURCE

- Patient Record
- Department of Defense Trauma

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting frequency will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the Chief of Trauma or equivalent's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

.

APPENDIX A: TRAUMA ANESTHESIA CHECKLIST

BEFORE PATIENT ARRIVAL

- ☐ Room temperature > 30˚C
- ☐ Warm IV line
- ☐ Machine check
- ☐ Airway equipment check
- ☐ Emergency medication check
- ☐ Blood Bank notified to have blood available per unit SOP

PATIENT ARRIVAL

- ☐ Patient identified for surgery as soon as possible
- ☐ Blood Bank notified to deliver blood per unit SOP
- ☐ Ensure large bore IV or CVC access
- ☐ Monitors (SaO2, BP, ECG)
- ☐ Pre-oxygenation

INDUCTION

- ☐ Sedative hypnotic (Ketamine vs. Propofol)
- ☐ Neuromuscular blockade (Rocuronium vs. succinylcholine)

INTUBATION

(Per Airway Management CPG)

- ☐ (+) ETCO2
- ☐ Place orogastric tube

ANESTHETIC

- ☐ Consider TIVA
- ☐ (Volatile anesthetic and/or benzodiazepine) + narcotic
- ☐ Insert additional IV access and/or arterial line if needed

RESUSCITATION

(per Damage Control Resuscitation CPG)

- ☐ Send baseline labs, type and cross if not yet done
- ☐ Follow MAP trends
- ☐ Goal FFP: PRBC: Plt 1:1:1 if Massive Transfusion. Use Cold Stored Whole Blood (if available)
- ☐ Activate walking blood bank to obtain Fresh Whole Blood (if needed)
- ☐ Goal urine output 0.5-1.0 mL/kg/hr
- ☐ Consider TXA if <3 hours from injury and at risk for hemorrhagic shock
- ☐ Consider calcium 1 gm
- ☐ Consider hydrocortisone 100 mg
- ☐ Consider vasopressin 2-4 IU + 0.04 IU/min
- ☐ Administer appropriate antibiotics
- ☐ Special considerations for TBI as indicated in *Severe Head Injury CPG*

CLOSING/POST-OPERATIVE

- ☐ Low volume ventilation per *Acute Respiratory Failure CPG*

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of Department of Defense (DoD) policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion of off-label uses in CPGs is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion of off-label uses in CPGs is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, the DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Aural Blast Injury/Acoustic Trauma and Hearing Loss (ID:05)

This CPG will help the reader to quickly identify and treat aural trauma and hearing loss, to prevent morbidity, and to preserve as much function as possible – even while in the combat theater.

INTRODUCTION

Acoustic trauma has continued to amass veteran disability at a 13-18% annual rate. Of the 2.35 million unique cases of auditory system disability at the end of FY 2013, approximately 870,000 are attributed to the Gulf War era and approximately 551,000 from exposure during operations in Iraq and Afghanistan.[1] Within the Department of Defense (DoD), 2% of the total force develops permanent injury annually, and 11-14% have unique episodes of temporary shifts in hearing. Historically, auditory injuries that are invisible and not life or limb threatening are not brought to the attention of medics, unless they are associated with other sever injuries, or are disabling in severity.[2]

The goal of this CPG is to elevate the awareness of noise threat, the prevalence of hazardous noise exposure, and the symptoms of acoustic trauma for purpose of facilitating early identification and early intervention of acoustic trauma. Improving outcomes for hearing requires developing a trusted surveillance and early referral and reporting system so that significant symptomatic exposures can be evaluated and diagnosed in a timely manner within therapeutic windows when intervention may mitigate injury progression, rather than current trends that put off consultations that delay care past the point of successful management. Improving the outcomes from acoustic trauma will preserve hearing capabilities in ranges conducive to continued high level function and performance.

INJURY OVERVIEW

For the purposes of this CPG, Service Members exposed to hazardous noise is impact noise or noise greater than (140dB) are at high risk for acoustic trauma and subsequent Hearing Loss (HL). Patients exposed to blasts are at risk for both aural and acoustic trauma.[(3-5)]

Hazardous noise causes injury to the hearing mechanisms in the inner ear. The symptoms of acoustic trauma are: hearing loss, tinnitus (ringing in the ear), aural fullness, recruitment (ear pain with loud noise), difficulty localizing sounds, difficulty hearing in a noisy background, and vertigo. Acoustic trauma may result in sensorineural hearing loss (SNHL) that is either temporary (temporary threshold shift, TTS) or permanent (permanent threshold shift, PTS). A TTS will resolve with time, while the time frame for hearing recovery is unique in every case, any SNHL that persists beyond 8 weeks after injury is most likely permanent and should be considered a PTS. There are no clinical predictors for which patients with a TTS will persist to develop PTS.

The ear, specifically the tympanic membrane (TM), is the most sensitive organ to primary blast injury (PBI). Blasts can perforate the TM. Risk of injury is determined by proximity to the source of the blast, as well as factors related to secondary, tertiary, and quaternary blast effects.[6] The signs and symptoms of a TM perforation include the signs and symptoms of SNHL as well as pain, bloody ear discharge, and conductive hearing loss (decreased ability to transmit sound through the middle ear to the inner ear,). TM perforations heal spontaneously in 80 to 94% of cases.[7] The smaller the size of the TM perforation, the greater the likelihood is of spontaneous closure. The majority of TM perforations that close spontaneously do so within the first 8 weeks after injury.[(8,9)] For these reasons, perforation rates in mass casualty situations may be under reported when limited resources are utilized for more significant polytraumatic cases. Because the tympanic membrane may be more at risk for damage than other body systems, it may likely be included in the non-immediate injuries deferred for later evaluation during which interval spontaneous healing may occur.[10] The more significant exposures are manifest in the immediate triage and may be the tympanic membrane perforations that are more refractory to spontaneous healing as noticed in the Boston marathon bombing where proximity to blast and significant nonotologic injuries were predictors of perforation.[11]

The ossicular chain may be injured as a result of PBI, with fracture of the ossicles or disarticulation of the chain, both of which can result in CHL with or without SNHL. TM perforations and middle ear injuries may heal with scarring that stiffens the ossicular chain also resulting in CHL. Blasts are noise hazards as well as explosive threats. The combination of a CHL with a SNHL is called a mixed hearing loss.

The temporal bone may also be fractured as a result of higher order blast injury, and these often are associated with secondary or tertiary blast effects.[12] Patients with temporal bone fractures may have lacerations in the ear canal or along the TM, resulting in either bloody otorrhea or hemotypanum (blood behind the TM).[13] They may also have SNHL or CHL, depending on the orientation of the fracture. A small number of these fractures (15%) will have an associated cerebral spinal fluid (CSF) leak.[14] These are termed CSF otorrhea (a leak from the auditory canal) or CSF rhinorrhea (a leak from the nose). The risk of meningitis within the first 7 days post injury ranges from 5-11%, but increases to as high as 88% if left untreated over time; therefore broad spectrum antibiotic prophylaxis and expert consultation are recommended.[(14-17)] Testing otorhinorrhea to distinguish between patients with bloody drainage containing CSF from those who have bloody drainage without CSF is insensitive unless assay for beta2-transferrin (a protein unique to CSF) is obtained, which is unlikely to be available in the deployed setting. Spontaneous closure of CSF leaks occurs in greater than 90% of cases, and is facilitated by bed rest – head of bed elevation - anti-strain precautions and stool softeners. Failures should be considered for lumbar drainage of CSF. Surgical management of CSF leaks should be considered in CSF otorhinorrhea that does not close with other measures.[18]

The facial nerve can be injured in temporal bone fractures.[19] Acute management of intratemporal facial nerve injury is to provide objective documentation of facial movement using the House-Brackmann grading scale.[20] Complete immediate paralysis of the face portends more significant injury to the nerve and should be referred for evaluation and possible surgical decompression to improve optimal outcomes for facial function. Significant weakness approaching complete paralysis will often recover completely. Incomplete or complete facial paralyses that preclude eyelid closure should be managed with measures that include eye protection (eye lid taping, ophthalmic tear substitutes and protective ointment). For significant facial pareses/paralyses, early administration of steroids should be provided if not contraindicated, and referral for management by an otolaryngologist is indicated.[21]

Dizziness expressed as unsteadiness or vertigo (spinning sensation) following a blast injury can be a result of traumatic brain injury, but is also often caused by injury to the inner ear, specifically benign paroxysmal positional vertigo (BPPV), damage to sensitive neuroepithelial rests within the inner ear, perilymphatic fistula, and other.[22] Other inner ear abnormalities may cause vertigo such as otic capsule violating temporal bone fractures, secondary infections of the inner ear or vestibular nerves, trauma induced endolymphatic hydrops, and activation of subclinical superior semicircular canal dehiscence.

EVALUATION & TREATMENT

All Service Members that develop **symptoms consistent with noise trauma** (acute tinnitus, muffled hearing, fullness in the ear) should be educated and directed to self-report for evaluation and possible treatment as soon as practicable. Patients exposed to hazardous noise occurring from exposure to battle (improvised explosive devices, rockets, and small arms fire) and all patients exposed to a blast should be asked specifically about hearing loss and tinnitus during their initial trauma evaluation, unless other more urgent treatment or mental status conditions do not allow. This should be documented as soon as safe evaluation permits. All patients presenting to concussion care centers should be evaluated for hearing loss and tinnitus. If there is debris in the External Auditory Canal (EAC) or in the middle ear (as seen through a TM perforation), treat the patient with a fluoroquinolone and steroid containing topical antibiotic (e.g., four (4) drops of ciprofloxacin/dexamethasone or ofloxacin in the affected ear three (3) times a day for seven (7) days). Do NOT irrigate the ear as it may provoke pain and vertigo, move debris medially in the canal and middle ear, and promote infection. Also, do not use any

topical drops containing aminoglycosides (i.e. the neomycin in Cortisporin) since these are ototoxic. Patients should observe strict dry ear precautions and keep ALL water out of the EAC until the TM perforation has healed or is repaired. Removal of debris should only be done by an ENT surgeon in order to avoid further injury to the EAC or the middle ear.

Hearing loss that persists 72 hours after acoustic trauma warrants a hearing test or audiogram. When hearing loss is present, individuals should be restricted from hazardous noise environments and kept on base, if possible. This is important to allow time for healing, and the inner ear is more susceptible to further noise-induced damage while it is under the oxidative stress and glutamate toxicity of an acute injury. A Service Member with hearing loss is less effective during missions and can negatively impact mission performance.

Vestibular trauma to the inner ear may manifest in vertigo. Please refer to the Veteran Affairs/DoD vestibular clinical recommendations for a detailed review of traumatic dizziness (http://hearing.health.mil/files/vestibclinpractrecs.pdf). All patients with positional vertigo and without other contraindicating injuries should undergo a Dix-Hallpike test, and an Epley or canalith repositioning maneuver if positive. (See Appendix A and Appendix B.)

ABSOLUTE INDICATIONS FOR SCREENING AUDIOGRAM (HEARING TEST)

All patients with subjective hearing loss and tinnitus following blast exposure should have the exposure documented, and should be evaluated by hearing testing as soon as possible. Hearing loss (either subjective or through screening audiograms) that persists for more than 72 hours after an acoustic trauma or blast injury warrants formal comprehensive hearing test or audiogram (including tympanometry, bone conducted thresholds, speech discrimination, and acoustic reflexes not evaluated by screening audiograms). Patients with TTS greater than 25 dB losses in three consecutive frequencies should be considered candidates for high dose oral and/or transtympanic steroid injections when not otherwise contraindicated. An oral steroid regimen of prednisone 60mg daily for 10 days followed by a two week taper, and transtympanic dexamethasone 24mg/ml repeating at 1-2 week intervals for up to three injections are warranted. Hearing response to treatment should be followed by audiometry, and additional injections guided by response to steroid. Patients with threshold shift greater than 60 dB on three consecutive frequencies for ten or more days after noise exposure are not likely to resolve spontaneously and are likely PTS losses. Hearing loss is detrimental to the patient's personal safety and effectiveness and may carry a comorbid vestibular deficit either clinically or sub clinically. Patients should be referred to ENT for evaluation and further testing. If ENT is not available in the specific Area of Operation (AOR), then patients should be evacuated to a higher level of care.

ABSOLUTE INDICATIONS FOR OTOLARYNGOLOGY (ENT) REFERRAL

- Temporal bone fracture with or without ear drainage.
- Persistent HL > 72 hours after acoustic trauma, or inability to perform duties due to perceived HL.
- TM perforation that has not resolved 8 weeks after injury. Referral for simple TM perforations without refractory drainage or significant SNHL should be delayed until 8 weeks after injury to allow for healing.
- Vertigo that does not resolve within 7 days after injury, even if episodic.
- Clear ear drainage.
- Persistent discolored ear drainage that does not resolve after 3 days of topical antibiotic steroid combination drop therapy.
- Facial nerve paralysis.
- On screening audiogram:

- Pure tone threshold average across 500, 1000, and 2000 Hz that is greater than 30 dB.
- Or any hearing threshold greater than 35 dB at 500, 1000, and 2000 Hz.
- Or any hearing threshold greater than 45 dB at 3000 Hz or 55dB at 4000 Hz.

Interpretation of the post-traumatic audiogram is facilitated by review of a baseline audiogram, if available.

RELATIVE INDICATIONS FOR OTOLARYNGOLOGY (ENT) REFERRAL

- Debris in the EAC that does not clear with topical ear drops.
- Inability to visualize the TM despite treatment with topical ear drops.
- Persistent dizziness, even if not true vertigo.
- Significant communication problems regardless of the hearing test results.
- Tinnitus that interferes with the patient's duty performance or lifestyle, regardless of hearing test results.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients exposed to a blast, and patients who develop symptoms consistent with noise trauma.

INTENT (EXPECTED OUTCOMES)

1. All patients with blast injury, with symptoms of acoustic trauma (e.g., tinnitus, vertigo, muffled hearing, and drainage from ear, fullness in the ear, blast injury or documented noise trauma) have documented tympanic membrane examination.
2. All patients with blast injury, with symptoms of acoustic trauma (e.g., tinnitus, vertigo, muffled hearing, and drainage from ear, fullness in the ear, blast injury or documented noise trauma) persisting greater than 72h have documented screening hearing test or audiogram.
3. All patients in the population of interest with absolute indications for ENT referral (per CPG) have a documented ENT evaluation.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who have a documented tympanic membrane exam.
2. Number and percentage of patients in the population of interest with hearing loss persisting >72h who have a hearing test or audiogram.
3. Number and percentage of patients in the population of interest with absolute indications for ENT referral who have a documented ENT examination.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

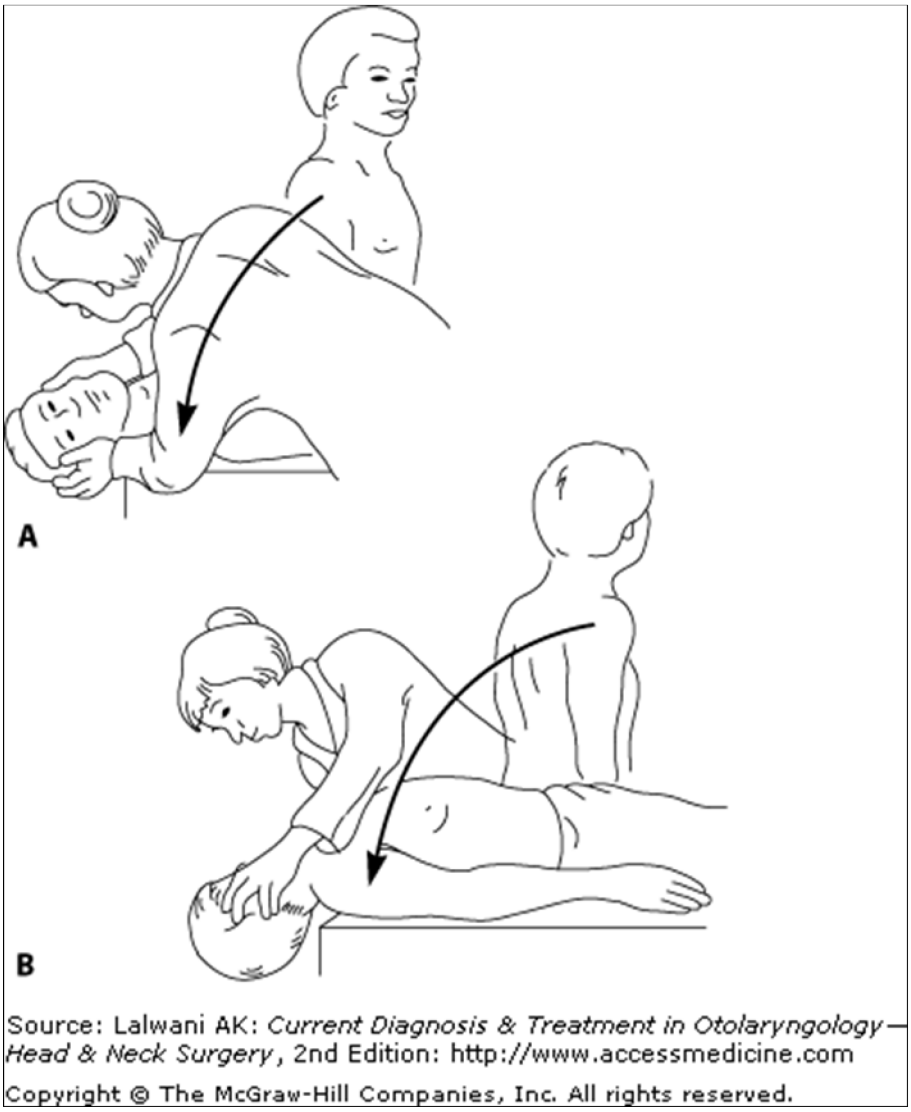
APPENDIX A: DIX-HALLPIKE TEST



Source: Lalwani AK: *Current Diagnosis & Treatment in Otolaryngology—Head & Neck Surgery*, 2nd Edition: http://www.accessmedicine.com

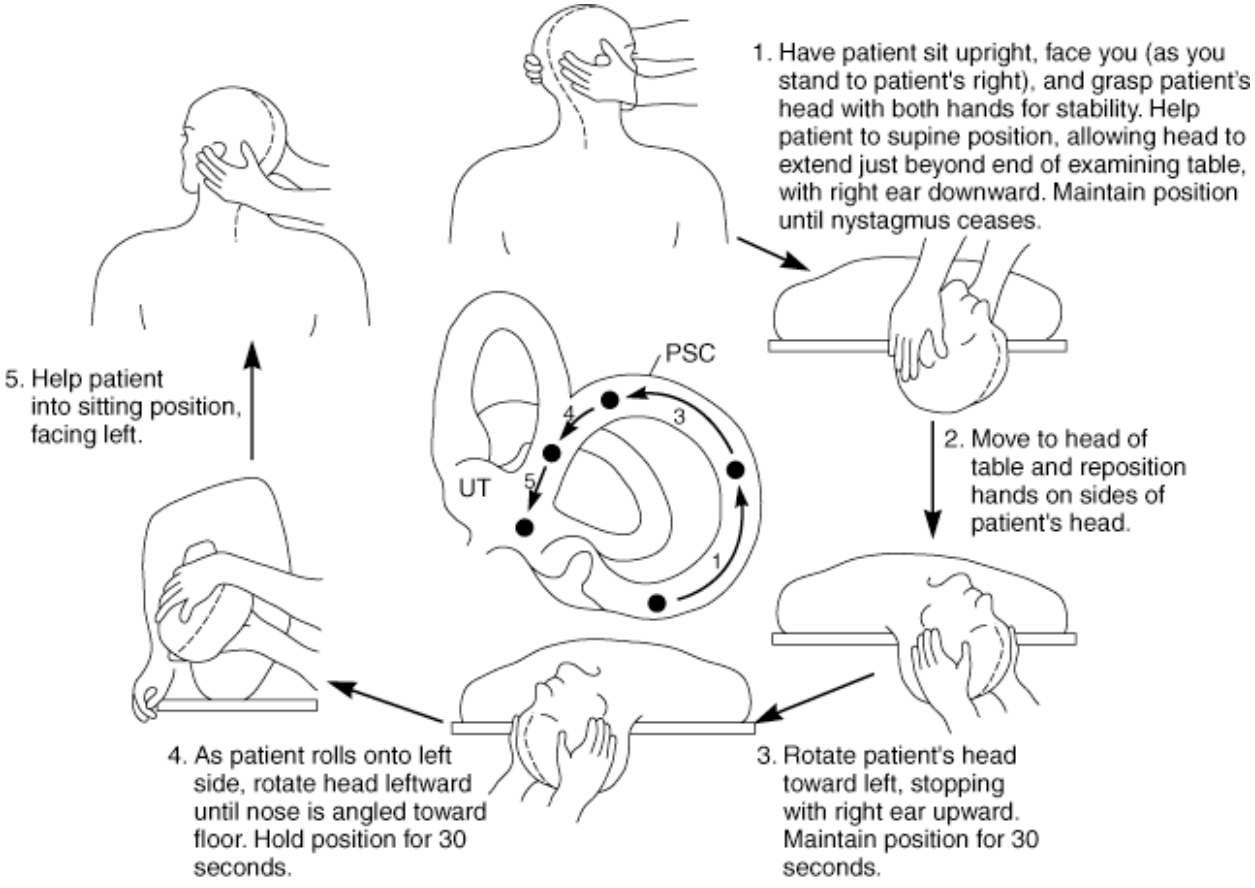
Copyright © The McGraw-Hill Companies, Inc. All rights reserved.

DIX-HALLPIKE TEST

A. For testing the right posterior semicircular canal, the patient sits on the exam table and turns his or her head to the right 45 degrees. This places the posterior semicircular canal in the sagittal plane. The examiner stands facing the patient on the patient's right side or behind the patient.

B. The patient is then moved by the examiner from the seated to the supine position with the head slightly hanging over the edge of the table. The right ear is down and the chin is pointing slightly up. The eyes are observed for the characteristic nystagmus.

APPENDIX B: EPLEY MANEUVER



1. Have patient sit upright, face you (as you stand to patient's right), and grasp patient's head with both hands for stability. Help patient to supine position, allowing head to extend just beyond end of examining table, with right ear downward. Maintain position until nystagmus ceases.
2. Move to head of table and reposition hands on sides of patient's head.
3. Rotate patient's head toward left, stopping with right ear upward. Maintain position for 30 seconds.
4. As patient rolls onto left side, rotate head leftward until nose is angled toward floor. Hold position for 30 seconds.
5. Help patient into sitting position, facing left.

EPLEY MANEUVER

The patient is taken through four moves, starting in the sitting position with the head turned at a 45° angle toward the affected side.

A. The patient is placed into the Dix-Hallpike position (supine with the affected ear down) until the vertigo and nystagmus subside.

B. The patient's head is then turned to the opposite side, causing the affected ear to be up and the unaffected ear to be down.

C. The whole body and head are then turned away from the affected side to a lateral decubitus position, with the head in a face-down position.

D. The last step is to bring the patient back to a sitting position with the head turned toward the unaffected shoulder.

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

SUMMARY OF RECOMMENDATIONS & GUIDELINES

- The intent of this Clinical Practice Guideline (CPG) is to provide guidance for Austere Resuscitative and Surgical Care (ARSC) teams, which are often comprised of conventional forces surgical units employed in support of special operations missions.
- All ARSC teams should receive ARSC-specific, team-centric pre-deployment readiness training to include medical aspects and operational aspects of ARSC, with the result that ARSC teams are capable of protecting themselves and their patients and function well in a tactical environment.
- The purpose of the ARSC team is to mitigate risk for the Operational Commander by providing surgical and resuscitative care for combat casualties. ARSC teams are smaller and more mobile compared to other conventional surgical assets and have less clinical capability and holding capacity. Realistic assessment of the risks and benefits of this capability must be clearly communicated to the Operational Commander.
- Limited resources and staffing require that medical decisions are made in the context of the following variables: time and distance to the next role of care, capability of the next role of care, availability of blood products, sterility, anticipation of further casualties, evacuation capability, security, mobility, and patient holding capacity.
- Patient care must focus on rapid triage, initial resuscitation with blood products, rapid control of hemorrhage and contamination with a damage control approach, and subsequent transfer to higher echelon.
- Ultrasound of the chest and abdomen in patients with penetrating trauma to chest, abdomen, or pelvis or severe blunt trauma should be performed to rule out life threatening injuries.
- A ruck-truck-house model, listed below, can help frame logistical considerations for planning purposes to maximize mobility and flexibility.
- Documentation (e.g., JTS Austere Trauma Resuscitation Record, operative note) must be completed for all patients treated by ARSC teams and submitted to the JTS or uploaded into Theater Medical Data Store (TMDS).

INTRODUCTION

The intent of the CPG is to provide small, conventional surgical teams both operational and clinical guidance for this unique ARSC environment. Small teams from every service have been tasked with the mission of supporting operational units (usually Special Operations Forces [SOF]) in far forward environments. The ARSC environment utilizes surgical capability outside of the conventional doctrinal guidance. The development of this CPG is not indicative of JTS support for non-doctrinal use of ultra-small teams with limited capabilities, but rather to provide guidance for teams that are deployed in support of missions that require ARSC to facilitate the best outcomes for casualties managed by ARSC teams.

It is recognized that teams are working in the ARSC environment, frequently without specific training for the unique challenges, both clinical and tactical, that these teams encounter. Small surgical teams have been increasingly utilized and have an evolving role in providing care to U.S. and partner forces on the battlefield over the last two decades of global conflict. The Task Force Commanders or their designees will be referred to as the Operational Command to represent all services throughout this document. Operational forces place high value on the support of surgical capability in their area of operations and may be constrained by policy to perform forward military operations within defined evacuation rings. During the course of current conflicts, U.S. Army

Forward Surgical Teams (FST) and others were split into ever smaller elements and employed outside of published doctrinal concepts in order to meet operational demand for close surgical support,[1-7] often in support of SOF. The demand for smaller and more mobile surgical teams has continued to grow and many different models have emerged over the last two decades. Examples include: the Joint Medical Augmentation Unit Surgical Resuscitative Team; Army Expeditionary Resuscitative Surgical Team and split Forward Resuscitative Surgical Team; the Air Force Ground Surgical Team and Special Operations Surgical Team; Navy Damage Control Surgical Team and Expeditionary Resuscitation Surgical System.[1-11]

There is no standard definition or joint doctrine specifying the exact capabilities of these small surgical teams. While this CPG has been developed based on ground combat support, the concepts can be applied to maritime environments. Recently, the Austere Surgery Teams Sub-Committee of the JTS Committee on Surgical Combat Casualty Care defined the care environment of these small teams as, "Austere Resuscitative and Surgical Care is advanced medical capability delivered by small teams with limited resources, often beyond traditional timelines of care, and bridging gaps in roles of care in order to enable forward military operations and mitigate risk to the force."[12] The goal of this guideline is to provide guidance for the leaders and personnel of ARSC teams who are tasked to deploy and provide advanced medical and surgical capability on the battlefield spanning the spectrum from point of injury (POI) up to conventional Role 2; noting that this environment of care has nuances from conventional/doctrinal surgical support. These teams are often comprised of conventional forces personnel in support of SOF missions and have a unique placement in the battlefield system of care; their ability to support these teams and remain small and agile is reliant on the proximity and capabilities of adjacent roles of care.

ARSC MISSION READINESS

Expertise in trauma care is the cornerstone for ARSC teams and trauma training to achieve and sustain clinical expertise of all team members is foundational. Historic abbreviated 'just-in-time' training for trauma care is highly discouraged. Combat trauma patients already present the most demanding challenges to an experienced trauma team in the unconstrained environment. ARSC team members should be selected to possess a mission-first mindset, perform well under duress, work effectively as part of a team, and demonstrate resilience to periods of sustained levels of stress. Individual members should be proficient in TCCC and their respective specialties of resuscitative, surgical, and post-op care of critically-ill trauma patients. Ideally, ARSC teams will achieve expertise by working routinely as a team in high volume, high quality trauma centers in order to develop trust, fluid team dynamics, and to cross train on key roles and tasks in order to maximize use of limited available hands.

It has been well recognized that certain teams supporting these missions may not maintain the appropriate clinical volume for skill sustainment. This fact emphasizes two elements of the current trauma system in the DoD: (1) maintaining surgical trauma skills while not deployed (2) keeping deployments short for individuals with life-saving critical skills that have been demonstrated to be perishable. It is important that deployed clinical and operational leadership recognize the value of personnel flexibility (intra-theater rotations) to ensure that providers get clinical exposure during deployments.

ARSC teams should be prepared to function outside of the boundaries of forward operating bases; therefore, success relies on proper integration with the operational mission. The ability to balance resuscitative trauma care within the tactical mission requirements and constraints is the greatest challenge. ARSC teams should undergo training to function in tactical environments, including training in survival, evasion, resistance, and escape, and be proficient in tactical communications and weapons management. Specific guidance from the supported ground force should guide the training requirements. Personnel must have the ability to defend themselves and their patients. Teams require expeditionary maneuverability with a compact resuscitative

surgical package that is rapidly deployable and collapsible. Pre-mission tactical training for the team should be supported by hospital and ground force leaders and include technical skills and knowledge, team training, and professional development.

Employing ad hoc teams without specialized equipment or more intensive, sustained pre-deployment and team-centric training specific for this mission presents both a risk-to-mission and risk-to-force, and is highly discouraged.[3,13,14] Being an asset in the operational environment, and not a liability, requires that ARSC team members have sufficient training to integrate with the supported operational force and throughout the entire en route chain of care. The smaller the ARSC team, the more technical and clinical expertise is required for all team members. Likewise, the farther forward the ARSC team deploys, the more tactical and clinical proficiency the team requires.

Mission planning is essential to effective employment of the ARSC team and begins well before deployment. Surgeon involvement with ARSC leadership is essential. ARSC leadership elements include: the officer in charge (OIC), senior surgeon, and senior enlisted member –they should be involved in all phases of the Joint Operations Planning Process. Communicate early and often with the line command in order to establish mutual trust and shared realistic expectations of the ARSC team's capabilities, limitations, and requirements for each individual mission while deployed. The Operational Command must be advised by the OIC and/or senior surgeon of the decreased capability (as compared to a conventional Role 2) that ARSCs can deliver, and accept the increased risk to their forces. The Command must be aware of the number of critically injured casualties that can be managed before personnel are overwhelmed or resources exhausted. Dedicated security from anticipated threats must be provided when the ARSC team is decisively engaged in patient care. Successful integration of resuscitative trauma care within the operational environment begins before the first patient contact.

OPERATIONAL INFLUENCES ON CLINICAL DECISION MAKING

Expert clinical decision-making in the austere environment is the most important asset the ARSC provides. It is multifactorial and may differ from traditional Role 2 and Role 3 settings based on the operational context and the time and distance to the next role of care. Availability of resources, personnel, blood products, sterility, anticipation of further casualties, evacuation capability,[15,16] security, mobility, and patient holding capacity must all be considered. Additionally, the dynamic nature of the tactical environment may result in frequent changes and constant situational awareness is required. Assumptions on duration of transport and time to intervention at next level of care may increase the risk for the patient, the team, and the mission. Therefore, in the majority of cases damage control surgery should be done prior to transport of a casualty. A patient should never be transported from this environment with any question of instability if there is any uncertainly of the transport timeline.

Surgeons are responsible to communicate real-time clinical risk assessments regarding tactical conditions, operational constraints and potential impact on patient outcomes. However, surgeons must recognize that the operational commander retains legal decision-making authority to assume risk and to decide when operational objectives and tactical mission requirements supersede the recommended clinical course of action. Priorities may be weighed against the current threat situation, necessity for tactical maneuver, opportunities to accomplish mission objectives, etc. ARSC team integration in operational planning phases not only determines the medical plan but clarifies the overall tactical intent and the Operational Commander's desired end state. This allows the Operational Command and ARSC team to make timely decisions to accomplish objectives and maximize critical care capabilities.

TACTICAL COMBAT CASUALTY CARE

The TCCC guidelines are foundational knowledge for austere providers at all levels of training, and as of 2019 TCCC Training is a requirement for all medical providers. Thorough knowledge of current TCCC guidelines will not only help surgical teams understand care provided at point of injury, but will also provide battle-tested options for care that is appropriate in austere environments, even for surgical teams. A thorough understanding of tourniquets, their associated complications, and recommendations for conversion to pressure dressings and removal in the austere environment is fundamental to TCCC and is not common knowledge for providers without prior tactical medical experience. TCCC airway management, pain management, and resuscitation recommendations have been implemented with a high degree of success.

Mass casualty (MASCAL) scenarios are especially challenging in resource-limited environments. A small number of casualties can quickly turn into a MASCAL for the austere team. Mastery of the concepts of TCCC will save lives in this setting.[17-23] Principles of dynamic triage must be utilized during all phases of care, including intraoperatively, and not be limited to the initial evaluation.[13] Proper triage results in the greatest good for the greatest number. This cannot be overstated. The burden of these decisions is heavy. Redundancy in triage and clinical skills is especially necessary for ARSC teams given that they do not have all the resources of a standard Role 2 and because every member will be task saturated. Realistic, challenging MASCAL and triage scenarios should be trained during pre-deployment in order to work through difficult decisions based on limited resources.

Austere teams should maximize the use of limited resources by restricting surgical interventions to damage control only, particularly when evacuation timelines are short. When evacuation timelines are delayed, more definitive or repeat surgeries may be required. For example, a vascular shunt may temporize arterial injury, but when evacuation is delayed beyond 24 hours, definitive vascular reconstruction or amputation may be indicated. When transferring patients to a host nation facility, the capability for definitive surgical care may be absent or unknown. This highlights the wide and complex spectrum of clinical care in the austere setting and emphasizes the importance of understanding time and distance to the next level of care with a clear knowledge of the transport capability as well as the receiving facility's capability.

When evacuation is delayed and patients are held by a surgical team after the initial resuscitative care, the surgeon must weigh the risks of definitive surgery against the risks of ischemia and infection. There are currently not enough outcome data available to make firm recommendations for patients being managed more than 72 hours in an austere environment.

DAMAGE CONTROL PROCEDURES

ARSC teams exist for unstable patients who cannot tolerate transport to a Role 2 (or next level of care); their function in the battlefield continuum of care is for the provision of early damage control resuscitation and surgery. ARSC teams should focus damage control principles as the primary approach for all surgical procedures which minimizes time, resources and personnel. This mindset and approach should be used for both traumatic and non-traumatic patients (such as appendicitis). There may be scenarios where the ARSC team will be the definitive level of care for host nation patients, however decision-making is still constrained by resource availability and by operational mission requirements.[24]

In most cases, emergency surgery for acute surgical diseases (e.g., acute cholecystitis and appendicitis) that do not clinically require a damage control strategy, should be temporized with antibiotics and expeditiously transferred to a higher level of care. If operational considerations require patients be held more than 24 hours,

or if the patient presents with sepsis or hemodynamic instability due to an intra-abdominal source, surgery may be indicated.

For elective or semi urgent cases, the evacuation chain should be utilized in communication with the operational commander and the theater trauma director. Give the significant resource limitations, only true emergencies should be considered at this level of care.

ANESTHESIA AND INTRAOPERATIVE MONITORING

Delivering safe anesthesia in the austere environment must account for available medical capabilities and the tactical situation.

Patient Monitoring

Monitoring under anesthesia ideally includes understanding normal physiology of a patient and using your hands and eyes to monitor your patient. Adjuncts in this environment are additional cardiac monitoring, blood pressure, pulse oximetry, temperature, and for a ventilated patient, inspired oxygen analysis and end-tidal carbon dioxide (ETCO2) measurement.[25] A range of devices are available to monitor vital signs with minimal space and maintenance. However, honing clinical skills to manually assess vital signs is important as monitoring devices may not always be available.

ETCO2: ETCO2 monitoring is an important capability as a physiologic indicator, even at the initial levels of care. The ETCO2 value is relevant during resuscitation and in TBI patients, in addition to its established role in verifying airway placement and monitoring ventilation.[25] Under controlled ventilation, the ETCO2 level can also be used to estimate changes in cardiac index, or cardiac output over time.[26] This knowledge can be applied within the clinical context, and can be used in cardiopulmonary resuscitation to predict patients who are more likely to achieve return of spontaneous circulation (PETCO2 >10mm Hg).[26] As such, ETCO2 can be useful during triage.

Ultrasound: The presence of sonographically identified cardiac activity at any point during trauma bay or intraoperative resuscitation is associated with increased survival to hospital admission.[27]

Invasive pressure monitoring: Small in-line devices (i.e. Centurion Compass®) have been used successfully for monitoring aortic occlusion during Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA). These can also be used to measure and trend central venous pressures, bladder pressures, or myofascial compartment pressures. See JTS Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) for hemorrhagic shock CPG, 06 Jul 2017.[28]

Perioperative Anesthetic Considerations

Definitive airway control is challenging in the trauma patient. It becomes increasingly difficult in the austere environment and requires a significant commitment of resources such as the need for a ventilator, continuous monitoring and sedation. When intubation is indicated, the timing should be optimized in order to conserve resources. Even with depressed Glasgow Coma Scale, if a patient remains spontaneously breathing, it may be preferable to support their respirations non-invasively while resuscitation is initiated. Resuscitation prior to induction of anesthesia in an unstable patient may prevent hemodynamic collapse. Alternative anesthetic techniques such as moderate sedation or peripheral nerve block may conserve resources. With respect to airway management, consider the capabilities of the transport personnel, their available respiratory and monitoring equipment en route, and the capability of the next level of care. In patients with a potential for airway compromise, ensure a definitive airway is established prior to transport. Considerations must be made

for supplemental oxygen delivery which can be challenging in this environment, an Austere Anesthesia CPG (under development) will address these issues specifically.

Maintenance of Anesthesia

The means to administer inhaled agents for the maintenance of anesthesia is not likely to be available in the austere setting. Electrical power and inspired gases used to drive vaporizers are problematic resources to obtain. Draw over methods could be considered, however can be challenging to titrate or administer when considering variables such as a non-spontaneously breathing patients or patient transportation. General anesthesia using a total intravenous anesthetic (TIVA) is a more effective means to provide adequate anesthesia and conserve equipment and resources. Practitioners should have an intimate knowledge of the benefits and limitations of intravenous anesthetic drugs available to allow for an effective, balanced anesthetic. Simple infusion pumps or quantitative drip sets can automate flow for prolonged infusions and providers should carefully select and train with their specific equipment. Since TIVA is commonly utilized in this environment, calculations and concentrations of the most commonly used drips have to be mastered by providers using this form of sedation and general anesthetic and the drip rates of Propofol, Fentanyl and Ketamine have to be well understood.

Regional Anesthesia Adjuncts

The capability to perform regional anesthetic techniques enhances the ARSC team mission. Experience in Iraq and Afghanistan has highlighted the value of early aggressive pain management in the combat casualty,[29] and reinforced the importance of multimodal pain management in the perioperative setting.[30,31] The use of regional anesthesia, either in conjunction with or instead of general anesthesia, may reduce the resources and personnel required for operative, postoperative, and subsequent en-route care. The risk of masking a developing compartment syndrome must be considered. Ultrasound or stimulator-based techniques can be used to perform a variety of nerve blocks. Intercostal nerve blocks can be used to decrease respiratory pain associated with thoracostomy tube or thoracotomy or multiple rib fractures.[32] A transversus abdominis plane block can be used as a part of multi-modal pain treatment to attempt early extubation after laparotomy, even in patients with a temporarily closed abdomen.[33]

Blood Transfusion Capability

In addition to surgical hemorrhage control, resuscitation with warmed blood is the most important intervention that the ARSC team can perform. Effective resuscitation of the trauma patient who has sustained massive blood loss consists of simultaneous hemorrhage control along with resuscitation to correct trauma-induced coagulopathy, acidosis, and hypothermia.[33] Resuscitation with blood products rather than crystalloid or vasopressor administration is the standard in trauma care; calcium administration should be early during the resuscitation. Treatment of acute coagulopathy of trauma is addressed with transfusion of whole blood, plasma, cryoprecipitate, and platelets, however blood products in the austere environment may be limited and platelets and cryoprecipitate will unlikely be available. Whole blood administration, preferably stored low titer type O whole blood (LTOWB), provides the most balanced resuscitation and is easier to administer as a single product for minimally staffed ARSC teams. The capability to draw warm fresh whole blood from prescreened donors should be optimized. Also, the capability to warm blood products during massive resuscitation is required, although there is not always standardized equipment to support this requirement, every effort should be made to ensure these teams deploy with at least 1 rapid fluid infuser with warming capabilities. Effective rapid transfusion and warming devices are necessary and require adequate power to support.

In general, an ARSC team should plan to ideally maintain at least 20 units of whole blood or red blood cells (RBCs) + plasma (20 of each blood component). Mission requirements will also dictate inventory levels of blood (mission support vs. area support). The ARSC teams must be in regular communication with the theater Joint

Blood Program Officer (JBPO) or Armed Service Blood Program Theater representative and keep their status updated (as much as possible) in TMDS to facilitate resupply. ARSC teams must have a well-rehearsed walking blood bank (WBB) capability. At times the WBB may rely on host national blood depending on the tactical and clinical environment. If using host nation blood supply, consideration must be given to endemic disease risk of donors and ability to perform rapid tests to mitigate risk. When supporting en route care missions, WBB is less feasible and stored blood is required depending on operational activity. Frequent communication with the supporting Blood Support Detachment and JBPO is essential.

SURGICAL AIRWAY MANAGEMENT

Airway obstruction represents 8% of potentially preventable prehospital deaths.[34] Multiple attempts at orotracheal intubation should be avoided, and providers should maintain a low threshold to surgically manage the airway. Complex facial injuries require airway management and hemorrhage control for temporary stabilization.[35] In this circumstance, obtaining an initial endotracheal tube or cricothyroidotomy is appropriate. As above, consider the level of the transport capability. Transferring a patient with significant maxillofacial injuries with a surgical airway as opposed to an orotracheal airway may be the safest option. It is important to have equipment for a surgical airway ready in the event that orotracheal intubation is unsuccessful. Always confirm airway placement with ETCO2.[36] See JTS Airway Management of Traumatic injuries CPG, 17 Jul 2017.[37]

NECK INJURIES

Hard indications for surgical neck exploration in the ARSC environment are no different than at the Role 2 or Role 3 and include 'hard signs' of vascular injury with active hemorrhage or expanding or pulsatile hematoma. However, because of the lack of imaging, lack of resources and the inherent challenge of these injuries – casualties without hard signs, should be transferred to a higher level of care as long as they have an acceptable airway for transport (this could be their native airway or a definitive airway). In some cases, exploration is indicated when airway injury is suspected based on subcutaneous emphysema or air bubbling through the wound,[38] however many cases of tracheal injury can be temporarily managed with endotracheal intubation with the cuff inflated below the level of injury. Be ready to immediately perform a surgical airway in these patients, as a relatively stable patient may have significant airway disruption. Proximal and distal vascular control is difficult for injuries approaching the base of the neck or skull base. In this environment, most penetrating wounds to the neck without immediate life-threatening hemorrhage should be transferred to a higher level of care for further diagnostic workup and subsequent formal surgical exploration. While penetration of the platysma alone is not an indication for neck exploration in the austere environment in the current trauma system, multiple factors must be taken into consideration (transport time, capabilities at sending and receiving facilities, the trauma system) as the level of injury may be difficult to ascertain without imaging. Maintain a low threshold to secure the patient's airway prior to transfer. Additionally, communication to the higher level of care should be established to discuss the plan for these casualties.

TRAUMATIC BRAIN INJURY

Non-neurosurgeons should be cautious when performing craniotomy or craniectomy in the austere setting, this is no different from a surgeon at a Role 2. However, in this far forward environment, medical management and craniectomy have even more challenges. Lack of appropriate training and experience may make operative therapy more dangerous than medical management alone. In the austere setting, every attempt should be made to maximize medical management (i.e. ETCO2 monitoring, hypertonic saline, bed positioning, airway management, sedation, paralysis, keeping the head elevated and midline. Discuss the patient with and transfer to a neurosurgeon as soon as clinically possible.[39] If transport is not possible, the provider should attempt to

seek the guidance of a neurosurgeon in real time. In the absence of proper imaging, burr holes or needle drainage of suspected epidural hematomas are discouraged. See JTS Emergency Cranial Procedures by Non-neurosurgeons in Deployed Setting CPG, 23 Apr 2018.[40]

OPHTHALMOLOGY

Trained ophthalmologists are never available in this environment and every attempt should be made to contact an ophthalmologists at the Role 3; however, given the nature of the ARSC teams, communication is not always feasible. Injuries to the globe should be covered with an occlusive shield and parental antibiotics and anti-emetics should be administered. These patients frequently experience severe nausea; oral medications should be avoided. It is imperative to avoid pressure to the globe, ensure nothing is directly touching the injured globe, and no intraocular medications are administered. See the JTS Ocular Injuries and Vision-Threatening Conditions in Prolonged Field Care CPG, 01 Dec 2017.[41] Lateral canthotomy and cantholysis should be performed if there is concern for retrobulbar hematoma or increased intraorbital pressure. In the rare circumstance that Telemedine support is available, it should be heavily utilized. Establish telemedicine consultation as soon as possible. AD.VI.S.OR, the Advanced VIrtual Support for OpeRational Forces system offers 24/7/365 on-demand real-time telemedicine consultations. https://prolongedfieldcare.org/telemed-resources-for-us-mil/

TORSO TRAUMA

Approximately 13% of combat casualty patients presented with injury patterns at risk of non-compressible torso hemorrhage (NCTH), and this was identified as a cause of death in 50-70% of patients assessed to have potentially survivable injuries in Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF).[35,42-44] Truncal injury was characterized as 36% thoracic and 64% abdominopelvic.[35] It is in this patient population that forward-positioned surgeons have the greatest potential to directly impact survival.[45-48] The ability to perform Extended Focused Assessment with Sonography for Trauma (E-FAST) for identification of intra-thoracic injury and intra-abdominal hemorrhage is required because X-ray and CT scan may be unavailable. Ultrasound has its limitations and has been documented as having a higher false positive and negative rates in penetrating trauma. In one study looking at combat trauma, FAST only had a sensitivity of 12% for intraabdominal injury requiring laparotomy;[49] this underscores the use of training to improve diagnostic sensitivity, as well as the challenges of these teams that do not have any additional diagnostic imaging. Diagnostic peritoneal lavage/diagnostic peritoneal aspiration (DPL/DPA) can be used to augment diagnostic capability when FAST results are equivocal, although DPL/DPA are only limited to evaluation of the peritoneal cavity. ARSC teams have to optimize requirement for ultrasound capability and providers must have the appropriate U.S. training. U.S. is limited for identification of pelvic or retroperitoneal hemorrhage, therefore a high index of suspicion should be maintained when the injury mechanism indicates potential retroperitoneal bleeding.

Although not proven with prospective outcome data, REBOA has shown potential in the austere environment as a bridge to prompt surgical intervention, to obtain rapid proximal vascular hemorrhage control, reduce blood transfusion requirements, improve exposure by reducing hemorrhage, facilitate rapid normalization of hemodynamics,[50] and as a force multiplier during MASCAL scenarios.[51,52] Early femoral arterial access (18 gauge A-line, 4 or 5 Fr. micropuncture) and monitoring can help identify patients who will die from hemorrhage earlier. Placing arterial access is strongly encouraged and does not require placement of a REBOA, but improves monitor. This can be upsized to the 7 Fr femoral sheath for balloon occlusion should the patient deteriorate. The sheath may be left in-situ connected to a pressure monitor during evacuation to higher levels of care or if repeat catheterization is probable, but comes at a risk of limb ischemia and even limb loss. Sheath complications are not uncommon and the sheath should be removed at the earliest time after the patient has demonstrated stability. After sheath removal the vascular must be evaluated to ensure that there is good distal perfusion.

While the sheath is in place, distal pulses must be followed closely. See the JTS Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) for Hemorrhagic Shock CPG, 06 Jul 2017.[28] All ARSC providers require REBOA training. There are multiple training courses available.

Laparotomy

Concern for NCTH with hemodynamic instability requires surgical intervention at the earliest opportunity that resources and personnel permit, this is no different from other roles of care. Damage control laparotomy is the standard in the unstable trauma patient and may be performed in forward environments.[13],[53] In the deployed setting, damage control surgery and temporary abdominal closure are recommended when significant intra-abdominal injuries are found.

In OIF and OEF, the rate of non-therapeutic laparotomy was as high as 32%.[54] A non-therapeutic laparotomy is likely safer than a potentially prolonged transfer in a casualty that might have a missed injury. These decisions are very challenging, but succumbing to injuries in flight is never acceptable. Selective non-operative management[55] should only be considered where CT scan, as well as, extended observation are possible.

Thoracotomy

The incidence of thoracic trauma in modern conflict is approximately 5%, with mortality ranging from 12%-24%.[44,56] Patients with severe thoracic trauma have a significant survival advantage if they reach surgical capability within one hour or less.[57-58] Thoracotomy should be performed when indicated with the damage control mindset and the goals of rapid control of hemorrhage and contamination. The chest may be temporarily packed and closed over chest tubes.

Cardiac Injury

Imaging is usually limited to a handheld ultrasound. Maintain a low threshold to perform a subxyphoid or transdiaphragmatic pericardial window if the injury pattern is concerning for mediastinal or cardiac injury. If there is blood in the pericardium, explore as indicated. See the JTS Wartime Thoracic Injury CPG, 26 Dec 2018.[59] Rarely, some patients with hemopericardium may present with normal hemodynamics which may represent a superficial injury to the myocardium and sternotomy may be avoided if the pericardial space is irrigated with warmed fluid, and the bleeding is noted to have stopped.[60-62] Place a closed suction drain and record output. A period of observation is recommended prior to transfer.

VASCULAR

Like every deployed surgeon, the ARSC surgeon should have training and experience in expeditious exposure of all named vessels to identify and control hemorrhage. The initial damage control and stabilization of injured vessels includes control of exsanguinating hemorrhage, recognition of extremity ischemia, rapid restoration of flow to the ischemic limb with vascular shunts, and fasciotomies to treat or prevent compartment syndrome.[13,62] All of the above, is exceptionally more difficult in the ARSC environment, emphasizing the importance of readiness and training for this skill set prior to deployment.

Shunt placement is a required skillset. When placing a shunt, thrombectomy of the distal vessel should be performed prior to shunt placement if vigorous back-bleeding is not present. Secure all shunts with suture as close to the vascular injury as possible to preserve native vessel length. Leaving all vessel loops used for proximal and distal control loosened and in place will allow the next surgeon to quickly identify relevant anatomy and provides rapid control of a vessel if the shunt dislodges in transport. Cover the operative field with dressings, and consider a temporary skin closure to protect the shunt. Primary patency rates are high for proximal shunts

(86%) and low for distal shunts (12%).[62] Primary repair of partially injured vessels, such as large veins, is preferable if greater than 50% stenosis can be avoided. Shunting of large veins is preferable to ligation when primary repair is not feasible and may increase patency rates of associated arterial shunts. Definitive reconstruction such as vein graft should be delayed to a higher level of care when possible.[13] If the vascular repair is associated with a fracture, immobilization with an external fixator is recommended; external fixation prior to definitive vascular shunting is recommended if the warm ischemia time allows. In the case of popliteal and femoral artery injuries, the use of shunts as opposed to primary amputation, even in an unstable patient, does not increase risk of death and improves overall amputation free survival.[63-64] Balloon catheters (REBOA or Fogarty) can be employed to provide temporary vascular control. Refer to the JTS Vascular Injury, 12 Aug 2016.[65]

Subclavian Vessels

This injury pattern carries a high mortality rate. Most venous bleeding and some arterial bleeding can be controlled with wound packing. A temporary skin closure over the packing may improve tamponade. Maneuvers to obtain proximal vascular control include intrathoracic exposures such as sternotomy, supraclavicular, clavicular resection, trap door approaches as well as retrograde placement of Fogarty catheter through the brachial artery or through the zone of injury. Additionally, inflating a Foley balloon within the wound track may provide tamponade, particularly if able to maintain compression against the clavicle or chest wall. A chest tube should be placed on the same side as the subclavian vascular injury if there is a concern for intrathoracic hemorrhage.

Inguinal Vessels

Contralateral placement of a REBOA catheter with aortic occlusion in zone 3 is a rapid and effective way to obtain temporary proximal control of a junctional groin injury. Extraperitoneal control of the iliac vessels above the level of the inguinal ligament also achieves proximal control of the injured vessel outside of the zone of injury, but a low threshold for intra-abdominal proximal control should be applied, given the often unpredictable trajectories of combat injuries.

Fasciotomy

Maintain a low threshold to perform fasciotomies for the combat injured extremity.[13] Delay in diagnosis of compartment syndrome can occur due to multiple patient handovers during the transport process.[13] Be proficient with techniques for both the upper and lower extremity – especially the common pitfalls: missing the deep posterior compartment in the lower extremity and not coming all the way across the carpal tunnel in the upper extremity. Even without evidence of compartment syndrome, early prophylactic fasciotomy may be considered in the setting of vascular injury with a temporary repair and may improve limb salvage rate, especially in patients who are going to be transported and do not have immediate access surgical care.[66]

EXTREMITY TRAUMA

Extremity trauma is the most common injury on the battlefield. Having proficiency with bony, soft tissue and vascular techniques in the extremities is extremely important for the ARSC surgeon – not always thoroughly trained in general surgery residencies. The austere surgeon must be familiar with all open surgical and non-surgical techniques to control hemorrhage and re-perfuse injured limbs. Transport of a patient with a tourniquet should be avoided. When tourniquets are left in place for more than 4-6 hours, the risk of severe rhabdomyolysis, kidney failure, limb loss, and death are high.[67] Closed reduction, splinting, and/or traction are often adequate temporary stabilization techniques of long bone fractures if these procedures adequately align the bony injury.

External Fixation

For combined orthopedic and vascular injuries, consider external fixation of long bone fractures after shunting and prior to definitive repair. Pelvic binder placement is effective for temporary control of most pelvic hemorrhage.[68] In delayed evacuation scenarios, pelvic binders should optimally remain in place no longer than 48-72 hours.

Mangled Extremity

Every effort should be made to temporize the mangled extremity and transfer the patient to a higher level of care. However, when blood product and resource availability are limited, limb salvage may not be feasible. Initial management of the mangled extremity includes hemorrhage control, irrigation, and debridement of clearly non-viable tissue. Traumatic amputations should not be formalized in the austere setting, though familiarity with formal amputations is required in order to anticipate future soft tissue coverage needs. Wounds should be left open in anticipation of repeated exploration and debridement. See JTS Amputation: Evaluation and Treatment CPG, 01 Jul 2016.[69]

Soft Tissue Wounds

Early debridement of soft tissue wounds and burns improves outcomes and morbidity. However, the ability to fully debride soft tissue wounds may be limited in the ARSC setting because of limited access to surgical energy devices, blood products, sterility, and irrigation fluid. Aggressive management of soft tissue injuries should be weighed against the available resources and operational considerations such as resupply and overall sustainment of the mission. In general, the ARSC team is not resourced to manage large soft tissue wounds that require serial debridement. Potable water is as effective as sterile fluid for surgical irrigation.[70] Sharp debridement is the standard of practice for soft tissue wounds. Commercial negative pressure dressings are unlikely to be available in the ARSC environment. Standard gauze (or hemostatic gauze) or occlusive dressings over closed suction drains are suitable for transport. See JTS Initial Management of War Wounds CPG, 25 Apr 2012[70] and JTS Acute Traumatic Wound Management in the Prolonged Field Care Setting CPG, 24 Jul 2017.[71]

ADDITIONAL CONSIDERATIONS

RESUSCITATION

Large bore IV access is one of the most critical components of initial resuscitation. With the IV stick, blood is used for Typing on an Eldon Card. All team members should be proficient in peripheral IV and IO placement. Initial resuscitation through an IO can be a bridge to IV placement. The DCR CPG algorithm should be followed for resuscitation. See the JTS Damage Control Resuscitation, 12 Jul 2019.[72] Ultrasound guided peripheral IV placement is another useful option. Additionally, it is recommended to become familiar with conversion of peripheral IV catheters to Rapid Infusion Catheters (Arrow RIC®). Central line access should be considered only when peripheral IV or IO access is limited or when multiple sites for infusion are not readily available. The majority of patients can be rapidly resuscitated through large bore peripheral IV or IO access. Rapid blood typing as part of the Walking Blood Bank, blood product storage, transfusion, and efficient blood warming are essential capabilities of ARSC teams.

BURNS

Protect the airway early; early intubation is necessary in patients with >40% TBSA burns, facial burns or this there is any concern for inhalation injury. Video laryngoscopy (i.e. GlideScope®) should be heavily utilized to obtain and early definitive airway and may help diagnose inhalational injuries in patients with facial burns. Burn resuscitation should be started as early as possible using the rule of 10s. See JTS Burn Care CPG, 11 May 2016.[73] The volume of IV resuscitation fluid available may be limited. Plasma may be used to supplement resuscitation fluid. Significant burns should be transferred rapidly to the next level of care. Maintain a low threshold to perform escharotomy early in the transport process, especially with circumferential full-thickness burns. Silverlon® is a lightweight burn dressing that can stay in place 3-5 days and is useful for other abrasions and shallow wounds as well. When burn dressings are not available, avoid debridement of blistered partial thickness burns and cover burns with dry sterile dressings. Maintain normothermia as burn patients are susceptible to hypothermia even in the warmest environments. Notify the USAISR Burn Center as early as possible (DSN 312-429-2876) or email: usarmy.jbsa.medcom-aisr.list.armyburncenter@health.mil.

HYPOTHERMIA

Maintenance of normothermia is crucial for survival of combat casualties. Active warming or cooling devices such as heaters or air conditioners have significant electrical power or fuel requirements and will not be available in the ARSC environment. Hypothermia management kits (HPMKs) should be frequently used, they contain chemical warming blankets that generate heat on exposure to air—these blankets should not be placed directly on the skin due to the risk of thermal burns. Hypothermia in the trauma patient is directly related to degree of blood loss. Hypothermia will continue until adequate blood volume is restored.

PEDIATRICS

ARSC teams may be required to care for pediatric patients including neonates, depending on the Medical Rules of Eligibility. This is a significant challenge for these teams; however, even though non-doctrinal, the unique mission requirements of these teams may result in them caring for pediatric patients. If this is the case, ensure age-specific medical supplies and equipment are available such as pediatric monitors, lines, tubes, and medications. While a Broselow bag may be too large to carry in this environment, they can be broken down and specific elements such as airway adjuncts and a Broselow™ tape can be carried to assist with caring for the pediatric population.

OBSTETRICS

Pregnant patients may present who meet medical rules of engagement for care. ARSC providers should be familiar with the anatomical changes that occur during pregnancy due to the gravid uterus. Ultrasound can be used to evaluate the fetus. Fetal distress is associated with a fetal heart rate of less than 100 beats per minute and is an indication of the need for continued maternal resuscitation, or even emergent fetal delivery. ARSC providers should be familiar with emergent obstetric procedures including cesarean section and surgical management of post-partum hemorrhage. ARSC providers should contact an obstetrician for guidance as able.

K9 DAMAGE CONTROL

Injured military working dogs (MWDs) may require urgent surgical stabilization. The MWD CPG, 12 Dec 2018.[74] outlines the unique clinical considerations for these patients. Always apply a muzzle (or improvised muzzle) early for safety. Consider having hair clippers and larger ET tubes (9-11 Fr) available for canine use as well as larger laryngoscopes (i.e. Miller blade size 4). The canine handler, unless injured, will help manage the care and will

have a card with weight-based medication doses specific to their canine. Standard tourniquets may be used for severe canine limb injuries, however elastic pressure dressings are typically effective and in some cases the tourniquets may not adjust to a small enough circumference to occlude blood flow. Predeployment MWD specific medical training is strongly recommended and in currently is a CENTCOM theater requirement. New recommendation regarding the K9 WBB exist and these teams (as well as all Role 2 and Role 3) should contact a theater Veterinarian when arriving in theater. If K9 blood is held on sight, then it must be in a separate cooler and location than human blood.

VENTILATOR MANAGEMENT

All team members should be facile with the use of the particular ventilator available. Refillable oxygen storage (liquid or gas) are heavy and a challenge to maintain and refill. Portable battery powered oxygen concentrators are an option but require power for continuous use. Additional ventilator management such as setting up an oxygen reservoir for a ventilator will be addressed in a future Austere Anesthesia CPG.

IMAGING

X-ray or cross-sectional imaging may not be available in the austere environment. Portable sonography may be the only imaging tool and miniaturized devices are available. Readiness and training for this skillset are required prior to deploying to an ARSC environment. Ultrasound will provide the ability to evaluate the torso for injuries (E-FAST), guide resuscitation, guide vascular access, assess for vascular flow, and to perform regional anesthetic techniques.

EXTERNAL ELECTRICAL POWER

The ability to provide quality care will depend heavily on electrical power. Early initiation of warmed blood products and patient normothermia are vital components of a successful trauma resuscitation. Maintenance of blood refrigeration and active warming and cooling devices (e.g., heaters, air-conditioners, blood warmers, plasma thawing devices) draw significant electrical power requirements. Regular maintenance and fuel requirements for power generators must be preplanned and communicated with the ground force commander, but are ultimately the responsibility of the surgical team.

CHEMICAL, BIOLOGICAL, RADIOLOGICAL AND NUCLEAR (CBRN)

ARSC teams should be prepared to protect and decontaminate themselves and there must be a plan for the patients and incoming casualties. While ARSC teams must have a treatment plan in place should they encounter a CBRN patient, they may not be equipped to manage this patient population. It is imperative to communicate this with the Operational Command that an ARSC team is not equipped or staffed for large scale patient decontamination that care timelines will extend during a CBRN event, and triage decisions may change significantly. See table below.

Table 1: CBRN Considerations for ARSC teams

CBRN Considerations for ARSC teams
• Develop hasty and deliberate decontamination plan (on arrival to a new site with all parties). • Conduct individual and team drills to practice donning personal protective equipment (PPE). • May use Nitrile gloves x 3 for protection– change outer glove if it becomes sticky or gummy. • Identify the nearest resource that has CBRN detection capabilities. • Identify large water source (55 gal drum or similar with hose). • Ample supply of rapid skin decontamination lotion. • Do not bring casualty into clinical facility until decontamination is complete. This is an element of proper triage. Anticipate loss of supplies and equipment used on patients prior to decontamination, and plan accordingly. • See JTS CBRN Injury Part I: Initial Response to CBRN Agents CPG [75].

BLOOD USE IN THE ARSC ENVIRONMENT

Blood is a resource that cannot be improvised and must be communicated to operational leadership as a mission critical requirement. Logistical factors with the ARSC team has to be considered even more so than at the Role 2 or Role 3. ARSC teams do not have dedicated personnel to manage the blood supply, storage, temperature regulation, accounting and resupply. Blood supply and resupply must be considered early and often. This is often managed through medical operations channels and requires close coordination with the combatant command blood program and regional blood logistic process. Maintaining stored blood products within a narrow temperature range and subsequently warming them in a timely manner are two of the greatest challenges of austere trauma medicine.[13,50] In an unstable and critically ill combat casualty, early balanced blood resuscitation (ideally whole blood) has been clearly shown to improve 72-hour mortality.[4,13,76-79] ARSC teams must anticipate blood requirements, work with the theater blood program manager to meet those requirements, plan for their own walking blood bank, and prepare for contingencies.[13,58]

Fresh Whole Blood (FWB) use in the combat casualty setting is associated with improved survival when compared to administration of packed red blood cells (PRBCs) and fresh frozen plasma (FFP) alone.[80] FWB eliminates the need for blood cooling, storage, and rewarming equipment, but carries increased risk of transmissible disease, and FWB donors may be limited in some operational environments. It is recommended, and will be doctrinal in an upcoming DoD Instruction, that anti-A and anti-B titer levels be drawn on all deploying personnel with type O blood in addition to FDA recommended infectious disease testing. This strategy provides a constant blood donor pool for contingencies. For U.S. casualties, FWB donors should be U.S. personnel, rarely from coalition, and from local nationals only in the most extreme cases. See the JTS Whole Blood Transfusion CPG, 15 May 2018 for detailed guidance.[81] Point of care testing for some transmittable diseases exist (e.g., human immunodeficiency virus), but the required time for interpretation may be prohibitive in patients in severe hemorrhagic shock. Have a plan in place for patients and donors who test positive for such diseases, and recognize that there may be significant cultural implications with local nationals and partner nation forces who test positive for such diseases.

The need to remain light and mobile further increases the challenge of retaining an adequate supply of blood products for mission support.[50] Portable battery-operated blood refrigerators and freezers are available (e.g. HemaCool®) but require mobility platforms to move over long distances and mechanical failures in hot and dusty environments may occur. Refrigerators and freezers require a constant and reliable power source, further increasing the team's weight and footprint and reducing maneuverability. Mission requirements for increased mobility may limit the size and number of refrigeration equipment and thus blood availability,[13] and vice versa.

RBC and frozen plasma are readily available at Role 2, Role 3 and at ARSC teams, but supply of platelet components are limited despite increasing use of cold stored platelets. Stored LTOWB and never-frozen liquid plasma are increasingly available via the ASBP theater blood distribution system. Freeze-Dried Plasma may be available for some ARSC missions supporting SOF. Options for acquiring blood outside official supply and resupply channels include walking blood bank drives (requires blood typing capability such as Eldon cards as well as citrate bags) and blood from the local "economy" such as local hospitals for use on host nation casualties should be considered when appropriate. Inform the theater JBPO if considering local host nation supply of blood products.

BLOOD WARMING

Conventional warming techniques for blood transfusion such as the Belmont® Rapid Infuser or plasma thawing devices draw significant power requirements and may be unavailable in the austere setting. Battery operated, in-line products are easily packed, however flow rates are inversely proportional to infusion temperature and may be inadequate for the trauma patient in severe hemorrhagic shock. Plasma thawing devices may be available in some equipment sets, but may not be suitable for small/highly mobile surgical teams or in the ARSC environment. There is no light, portable, approved plasma-thawing device. Portable water heaters and thermometers can be used to create a 30-37oC bath of water to thaw FFP and warm PRBCs to the appropriate temperature of 37oC; however, they are not FDA approved for this use. Approximately 10 percent of FFP bags may break during thawing and this should be factored into the supply. Pre-thawing frozen plasma saves time in the acute setting but once thawed, plasma must be used within 5 days.

WALKING BLOOD BANK

Every ARSC team member must be trained to draw and transfuse fresh whole blood, and must be able to recognize and manage transfusion reactions. Recruitment and blood typing of potential blood donors may take time, so early initiation of walking blood bank is recommended for patients with the suspected need for massive transfusion. Fresh whole blood transfusion must be type-specific, unless the donor has been pre-designated low-titer type O by laboratory testing. All low-titer type O donors must provide documentation of titer-testing prior to donation. See the JTS Whole Blood Transfusion CPG, 15 May 2018.[81] Standard equipment sets should contain blood drawing kits. Ensure that Eldon cards and point-of-care infectious disease testing kits are available and team members are trained on their use. Ensure a reliable system for marking and numbering: 1) individual donors, 2) blood donor bags, and 3) Eldon cards.

LOGISTICAL CONSIDERATIONS

Packing for ARSC missions can be framed usefully by the Ruck-Truck-House model developed by SOF medics,[82] which is a modular approach to mission planning based on cube and weight constraints. As building blocks, each phase of this supply model builds upon itself, with Ruck capabilities intrinsic to Truck, and Truck capabilities intrinsic to House. The term Ruck-Truck-House refers to the cube and weight of the mission equipment and not

necessarily to the mobility platform. For example, 'Ruck' missions may be performed from a truck, and 'Truck' missions are often conducted via rotary wing platforms.

Specific team member composition of each team is based on multiple variables, and specific staffing recommendations are outside the scope of this practice guideline. Generally, ARSC teams should be prepared to scale their team size according to mission requirements dictated by the Operational Command. A Ruck team may be the smallest number of personnel of any given ARSC team that still provides a minimal, functional capability, while a House team may be the maximum number of personnel with maximal capability. Limitations of scaled teams must be clearly articulated to the Operational Command in order to accurately communicate inherent risk.

RUCK

The Ruck model is the most mobile pack out, as supplies and equipment are limited to what can be carried on each team member's back. It is well understood, that this is not the ideal environment for surgical care; however, mission requirements occasionally dictate this capability. When it comes to surgical intervention, or no intervention and likely casualty death, this substandard option becomes a mission requirement. Due to its inherent limitations on resources, the Ruck model requires the highest levels of clinical skill, tactical proficiency, and teamwork, and personnel must be highly trained in all above areas for mission success. Medical planners and the surgeon must clearly communicate the clinical and other limitations to mission planners and the supported Operational Command in order to conduct appropriate risk mitigation. The Ruck model fits onto most transportation platforms. Although emergency surgery may be performed with this model, it is generally capable of providing temporary support for only one critical patient with no capacity to hold critically ill patients for any length of time. Blood products are extremely limited and the lack of power and electricity prevents use of blood storage and cooling, blood warming, and electronic patient warming devices. As a result of these limitations, rapid patient evacuation to the next level of care is vital and urgent resupply must occur in order to continue the mission. Alternatively, the plan may include performance of en route care and return to base upon mission completion. Additionally, communications are limited to personal radios and team security must be provided by the supported unit during clinical care.

TRUCK

The Truck model is also very mobile, capable of set up or collapse within minutes, and can be transported to a fixed location. Although this model may have greater capability than the Ruck model, its limitations must be carefully considered and communicated to planners and commanders in order not to fail expectations placed upon it. It includes each team members' ruck and as many additional supplies and equipment that can fit onto the mission's mobility platforms, depending on the mission need. This model may be able to treat and sustain more patients but is also limited by power and electricity, blood storage, and fluid volume. Although supplies are increased, it is still dependent upon a rapid evacuation and resupply chain if heavy casualties are encountered or it is intended to perform a static mission.

HOUSE

The House model is far less mobile, as it refers to a fixed location where the full equipment loadout of an ARSC team can be established and is only feasible to be maintained at a team house, firebase, or other mission support site. This model provides the highest level of care organic to the team and has a greater patient capacity. Continuous operations may be sustainable with casualty evacuation and resupply of blood and other Class VIII. Additional requirements for full operational capability include power and electricity for blood cooling

and storage, blood warming and infusion, patient warming, water for steam sterilization and hygiene, and other requirements. Open communication of requirements, capabilities and limitations to planners and commanders will enable mission success.

In all three models, challenges are magnified with supply and resupply limitations, blood availability, and prolonged hold time, transport time to next level of care, personnel available to help, and more. It is understood that this is not the ideal environment to care for surgical patients and that certain severe injuries will not be survivable. As emphasized above, the limited capabilities of these teams have to be understood by mission planners and operational commanders. Clinical experts including the senior surgeon should be involved in medical planning of mission support in order to ensure that critical supply requirements and limitations are addressed, clearly articulated, and solutions are developed within mission constraints. Involve planners and the Operational Command early and often in mission planning to understand command requirements, mitigate risks, and shape expectations for success. See Appendix A for sample packing lists for each model.

Many mission variables impact what is ultimately packed into the finite cube and weight requirements for each model. See Table 2 below for some of the variables to consider when planning for logistical support of ARSC missions.

Table 2: Variables to consider when planning logistical support for ARSC missions

Variables to consider when planning logistical support for ARSC missions	
ARSC team composition	• Number and type of medical personnel on the ARSC team • Team members' specialties, experiences, capabilities, preferences
Patient variables	• Types of patients (friendly combatants, enemy, civilian, pediatric, geriatric, MWDs)
Mission	• Operational Command intent • Security situation (i.e. expected tactical risk to medical personnel) • Length of mission • Number of expected casualties, number of troops at risk • Communication capabilities of medics and next levels of care • Space available for equipment • Max/min equipment weight requirements • Security element for the ARSC team • Task force composition (joint, combined) and service, state or national caveats • Team sustainment requirements
Evacuation	• Capability, time, distance from forward medics • Capability of the evacuation platform (CASEVAC vs MEDEVAC vs CCATT) • Capability, time, distance to next level of care

Variables to consider when planning logistical support for ARSC missions	
Environmental	• AO-specific medical concerns • Night vs day operations • Cold vs hot environments • Indoors vs outdoors • Physical and human terrain • Security environment
Resupply	• Emergent and routine time and processes for resupply of blood products and Class VIII

RESUPPLY

Resupply should be categorized as Mission Critical, Mission Essential, and Mission Enhancing for planning and communicating purposes. The category of medical supply or equipment items may change depending on the mission.

- **Mission Critical**: There is high risk of mission failure without these items.
- **Mission Essential**: There may still be significant impact but less risk of mission failure if lacking these items.
- **Mission Enhancing**: There is low risk of mission failure if lacking these items.

The following subsets may require separate and deliberate logistical planning.

- **Mission Critical, consumable**: there simply are not ways to improvise shortfalls on a few things (i.e. blood products, citrate bags, IV calcium, key anesthetic medications)
- **Mission Critical, durable with lifespan**: replacement instruments, litters, replacement medical electronics such as ventilators, monitors, ultrasound, Doppler probe, suction, etc.

Frequent high use. May be improvised: laparotomy sponges, TCCC equipment, OR towels and drapes, dressings, flushes, syringes, IV catheters, IV tubing, HPMKs, suture, lines, tubes, pain medications, antibiotics, etc.

A best practice is to plan with the supported unit's logistical support personnel in order to increase available assets for resupply and shorten the time required to execute. Educate the supported unit on movement requirements and limitations of critical supplies in order to facilitate timely and accurate decisions if a medical representative is not available at the higher level of command. Establish push and pull rapid resupply packages, often called "speed balls," at the resupply base with focus on medications and expendables rather than durable equipment. Establish and practice supporting procedures in order for resupply to function well, and maintain abundant medical supply stocks for unexpected requirements. Depending on the mission, consider incorporating non-U.S. resupply resources into medical logistics planning including intergovernmental organizations, non-governmental organizations, and host nation facilities and services. Such schemes may optimize coalition or advise, assist, and accompany missions where the population at risk may be primarily host or foreign country nationals.

SPECIFIC LOGISTICAL CONCERNS

Surgical Sets

Traditional Role 2 surgical sets are bulky, difficult to access, and redundant.[3,83] Surgeons and surgical technologists should work together to design sets that support their specific mission. In general, hold and evacuation times are directly proportional to the degree of care to be rendered, and subsequently, the amount of equipment required. See Appendix A for packing considerations organized by the Ruck-Truck-House model.

Anesthesia Equipment

Equipment should be mobile and adaptable to a variety of surgical cases. TIVA and regional anesthetic strategies are mobile and light. Additionally, regional anesthetics will decrease requirements for systemic pain medication and lessen the concern for airway compromise and management. The use of regional anesthesia in patients at risk for compartment syndrome is controversial; although the data is sparse, there is no evidence that peripheral nerve blocks delay the diagnosis.[84]

Nursing Equipment

Nursing equipment is often single use, disposable and requires frequent resupply (i.e. IV catheters, IV tubing, syringes). Careful reuse of nursing items for the same patient will minimize waste. Long term nursing supplies are not necessary since the ARSC teams do not have holding capacity and rely heavily on expeditious transport to the next level of care.

Instrument Sterilization

There are three principal methods to sterilize instruments including autoclave or steam sterilization, exposure to dry heat, and chemical antiseptics. Boiling is regarded as unreliable.[85] Mechanical or steam sterilizing devices are large, require high power input, and require several hours to clean, dry, and cool instruments. If sterilization devices are not available on site, instrument sets may be autoclaved or steam sterilized at a base of operations and turned over between missions. Careful planning should be used in packaging instrument sets so that not all instruments are opened and contaminated at once.[83] The minimum standard for instrument decontamination is application of enzymatic cleaner followed by disinfection with an antiseptic, which can be achieved with a number of solutions including formaldehyde, glutaraldehyde (Cidex®), or chlorhexidine. Refer to the manufacturer's standards for time of solution contact and other considerations. In order to preserve resources, certain disposable items such as surgical staplers, clip appliers, or cautery pencils may be disinfected in chemical solution. Cautery grounding pads may be cleaned and reused with germidical wipes; while not ideal, this is the reality of the ARSC environment.

Power Requirements

The medical team must communicate power requirements to the supported element. Medical electronics and blood storage require power. Planning considerations include the size of the generator, voltage output (i.e. 110V vs 220V), maximum ampere load, optimal and maximum wattage operating ranges, type of fuel used, amount of fuel required for the mission, and maintenance plans. Other considerations include the total power required for all electrical equipment, the daily fuel consumption, and the capacity in amperes of the largest available circuit breaker needed to power a heating element or other high energy device. 110V vs 220V power outputs and devices must be carefully matched to provide adequate power to medical equipment and prevent destruction of critical electronic equipment. Be careful to maintain an ample supply of fuses for important electronic equipment. Note that each piece of equipment has unique and specific fuses that are not universal to each

other and are prohibitively difficult to find on the local economy in most deployed locations. See Table 3 below for mission critical tasks and equipment that require power.

Medical Waste Disposal

Field hospital medical waste has been estimated to be an average of 1.5 to 3 kg of waste per patient per day.[86] ARSC planners should anticipate considerably more waste in the ARSC setting given the critical nature of patients with wartime injuries. Team members should be sensitive to local religious customs when disposing of anatomic waste.[86] The World Health Organization (WHO) recommends appropriate disposal of potentially infectious biological waste by either steam sterilization or high temperature incineration.[85] Burying waste is an option but consideration should be given to avoid pollution of the environment and water sources.[85-86] Establish a safe system to dispose of sharps. The International Committee of Red Cross Manual of Medical Waste Management is an excellent resource and provides specific guidance.[86]

Table 3: Mission critical tasks and equipment that may require power

Mission critical tasks and equipment that may require power		
Ruck—	Patient warming	HPMK, ready heats, wool or space blankets
	Blood cooling	Person-portable preconditioned coolers
	Blood warming	Small battery powered in-line products
	Medical electronics	Battery powered portable ventilator, monitors, and ultrasound
	Electrical power	Plan for person-portable, battery operated equipment
	Lights	Battery operated head lamps (consider equipment that uses standard batteries such as C123, AA, AAA etc. as opposed to nonstandard rechargeable lithium batteries as replacement batteries are more easily acquired)
	Communications	Battery powered radios
	Personal electronics	Minimal battery power only
Truck –	Patient warming	HPMK, ready heats, wool or space blankets
	Blood cooling	Coolers with wet ice for blood or dry ice for plasma, battery powered man portable blood fridges (e.g., HemaCool®)
	Blood warming	Recommend Belmont® Rapid Infuser or plasma thawing devices if power capability allows; if unable to support Belmont, utilize in-line device.
	Medical electronics (monitors)	Battery power with recharging cords – stress 110V vs 220V awareness
	Electrical power	Plan for Generator size 5kW-20kW and associated fuel requirement
	Lights	Battery operated head lamps, person-portable free-standing LED spot lights
	Communications	Vehicle mounted radio
	Personal electronics	Minimal rechargeable
House –	Patient warming	HPMK, ready heats, wool blankets, Bair hugger, consider wall space/area heating units with understanding that these have tremendous power requirement
	Blood cooling	Multiple battery powered portable blood fridges (e.g., HemaCool®), ensure backup power source is available should primary power source fail.

Mission critical tasks and equipment that may require power		
	Blood warming	Recommend Belmont® Rapid Infuser or plasma thawing devices if power capability allows; if unable to support Belmont, utilize in-line device.
	Medical electronics (monitors)	In line power, stress 110v vs 220v awareness
	Electrical power	Central power vs large generator
	Lights	Battery operated head lamps, person-portable free-standing spot lights, wall mounted lights
	Communications	Non-classified Internet Protocol (IP) Router Network / Secret Internet Protocol Router Network / WiFi (choice)
	Personal electronics	Choice

DOCUMENTATION

Accurate, and complete documentation promotes patient safety, and facilitates patient transfer, handover, and continuity of care. Documentation is required at all levels of care and can be challenging. In the ARSC environment, documentation is essential not just as part of a clinical standard but secondary to the need to further define, refine, and understand the limitations of this battlefield capability. The relatively low volume of causalities these teams have managed combined with the paucity of documentation received for Performance Improvement analysis makes understand the true capability and capacity of ARSC teams a challenge. Additionally, appropriate and reliable analysis requires accurate and complete data, which will then, allow more appropriate medical planning. In some cases, documentation and transmission is challenging due to a lack of communication equipment that enables reliable communications with higher levels of medical care. The ARSC environment is resource and personnel limited, and time must be committed to complete documentation on all patients. Experience has shown that in the setting of a MASCAL (when taking time to document seems the most challenging), proper documentation aids with communication, decreases redundant evaluations, avoids errors, and ensures complete care. Consider language barriers with documentation. In unconventional warfare and depending on the unit the ARSC team is supporting, using patient identifiers may not be permitted. If caring for host national casualties, using non U.S. forms in their native language may be beneficial medically and practically.

The JTS MASCAL/Austere Trauma Resuscitation Record and an operative note and anesthesia record for surgical patients is the minimum required documentation for all patients. Minimum documentation includes mechanism of injury, injuries identified, signs and symptoms, and treatments, vital signs, neurologic status, medications, and interventions provided. Follow the Combatant Command or regional standard naming convention for trauma pseudo names and maintain one consistent name for each patient during transfers. This improves continuity of care, patient tracking, blood resupply, and outcome analysis. In the operational setting include ethnicity, unit affiliation, and geographic location of injury as able. Use the JTS Burn Resuscitation Flow Sheet for major burns and prolonged field care flow sheet for prolonged care. When evacuating to higher level of care, records should be transferred with the patient. A photograph or copy of the record should be kept by the surgical team in the event the record is lost. When documentation cannot be completed prior to patient evacuation, complete the documentation immediately after evacuation and send it electronically to the next level of care as soon as able. Submit patient records to the DoD Trauma Registry (DoDTR) via dha.jbsa.healthcare-ops.list.jts-trauma-registry@health.mil or to the closest Role 3 or 4 medical treatment facility patient administration as soon as able. Keep a log of all trauma patients and submit to the DoDTR.

PERFORMANCE IMPROVEMENT (PI) MONITORING

Patient population: All patients treated by ARSC team

INTENT (EXPECTED OUTCOMES)

- ARSC teams will receive ARSC-specific, team-centric pre-deployment readiness training to include medical aspects and operational aspects of ARSC.
- Documentation is completed for all patients treated by ARSC teams (e.g., using the JTS Austere Trauma Resuscitation Record and an operative note) and submitted to the JTS or uploaded into the TMDS.
- Ultrasound of the chest and abdomen is performed and documented for patients with penetrating trauma to chest, abdomen, or pelvis or severe blunt trauma in order to rule out life threats.

PERFORMANCE ADHERENCE MEASURES

- All ARSC teams receive ARSC-specific training through a designated course or unit-specific training.
- Documentation is received by the next role of care and JTS for all patients treated by ARSC teams to include:
- Trauma Resuscitation Record
- Operative note if applicable
- Anesthesia Record if applicable
- An ultrasound of chest and abdomen is documented for all patients with penetrating trauma to chest, abdomen, or pelvis (gunshot wound or blast) or severe blunt trauma.
- Tourniquet times are documented (placement and removal times).
- All tourniquets are removed and bleeding controlled prior to transfer from a surgical capability.

DATA SOURCES

- Patient Record
- DoDTR

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief, JTS Program Manager, and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

ACKNOWLEDGMENTS

Defense Committee on Surgical Combat Casualty Care (CoSCCC)

APPENDIX A: ARSC EQUIPMENT CONSIDERATIONS

The following equipment lists are not complete packing lists. Teams should pack according to mission requirements, with expected numbers and types of patients significantly impacting quantities of medications and supplies.

For specific surgical instrument recommendations, please refer to: Hale DF, Sexton JC, Benavides LC, Benavides JM, Lundy JB. Surgical Instrument Sets for Special Operations Expeditionary Surgical Teams. J Spec Oper Med. Fall 2017;17(3):40-45. https://www.jsomonline.org/JournalArticles/20173.php#Article708

Disclosure: This CPG, the U.S. Air Force, U.S. Army, U.S. Navy, and DoD does not endorse or promote any specific products.

Ruck model—Plan for 1-2 surgical patients with 80% of combat trauma injury patterns	
TCCC equipment	• Litter • Tourniquets • Dressings, splints (e.g. Combat Gauze®, ACE, medical tape, Coban™, Kerlix™) • Needle Decompression catheters • Airway equipment (e.g. oropharyngeal airways, nasopharyngeal airways, definitive airways, AMBU bag, etc.) • Muzzle and large ETTs for MWD use
Nursing equipment	• Personal Protective Equipment • IV start kits, IO devices, extension tubing, Blood tubing • Syringes/flushes • IV fluids • Assorted lines/tubes/drains • Walking Blood Bank supplies (citrate bags, Eldon cards)
Airway and anesthesia equipment	• Airway instrumentation • Ventilation equipment • Regional anesthetic block needles • Dial-a-flow (infusion set) • Centurion pressure transducer • Non-elastic bougie
Medications	• Tranexamic acid • IV Calcium • Anesthetics • IV and PO Analgesics • IV and PO Antibiotics • ACLS medications • Antiepileptics • IV Fluids (including hypertonic saline for TBI) • Assorted ‘sick call’ meds

Ruck model—Plan for 1-2 surgical patients with 80% of combat trauma injury patterns (continued)	
Surgical instruments	• Major Instrument Set • Chest set with rib-spreader and Lebsche knife • Limited Vascular set – a few fine instruments and vascular clamps • Orthopedic bone saw (Gigli wires are intended to be single use, are fragile, and are difficult to re-sterilize)
Suture material	• Absorbable suture, given high likelihood of contaminated wounds • Heavy PDS for fascia • Fine Prolene for vascular repair • Fine PDS for urologic and airway repairs • Absorbable free ties for ligation of small vessels • Heavy silk to secure tubes/drains • Umbilical tape • Heavy chromic for hepatic repairs • Bone wax for amputations • Vessel loops, large and small • Pledgets
Other surgical equipment	• Head Lamps • Cricothyroidotomy Kit • GIA Staplers with reloads • Topical Hemostatic Agents • Surgical Sponges (Ample supply of sponges cannot be overstated or overemphasized) • Vascular Shunts • REBOA catheter and introducer kit • Chest Tubes, chest seals, and Heimlich valves • Skin staplers • Temporary Abdominal Closure device (e.g., Ioban)
Electronics	• Portable, battery powered ETCO2 monitor • Video laryngoscope (GlideScope®) • Portable, battery powered pulse ox monitor • Portable, battery powered vital signs monitor • Blood cooling container (e.g., golden hour box) • Hand-held Doppler device • Hand-held ultrasound device • Portable ventilator • In-line IVF/blood warming device • Clippers for MWD use

Operational equipment	• Internal and external communication equipment (e.g., hand-held encrypted radios, Peltors) • Eye protection, ear protection • Night vision equipment • Headlamp capable of red/green/blue light • Navigation tool(s) (e.g., lenzatic compass, GPS) • Survival equipment (e.g., blood chit, escape and evasion kit) • Tactical protective equipment (body armor), IFAK • Personal weapons and ammunition

Truck model—Pack for 2-5 surgical patients with 80% of injury patterns. Includes increased quantities of all Ruck items.	
Added TCCC equipment	• Litters • MASCAL kit • CBRNE kit
Added anesthetic equipment	• Oxygen • OG tubes • RIC catheters
Added surgical instruments	• Consider 2 or more of each instrument set • Limited external fixator set
Other surgical equipment	• Operating Table/Litter Stands + Arm Boards • Broselow bag
Added electronics	• Point of care laboratory testing (iSTAT requires regular maintenance including calibration and cartridges must be temperature controlled) • Battery-powered blood fridges and/or freezers • Belmont Rapid Infuser
Added operational equipment	• Person-portable generator to power electronics with maintenance kit • Space heater • Fuel for generator • Tentage to set up patient care space

House model—This model may allow for true surgical sets. The number of sets required will depend on how many simultaneous OR tables the site is intended to provide. Consider frequency and time required to re-sterilize instruments. Includes increased quantities of all Truck items.	
Anesthetic equipment	• MAC catheters
Medications	• Increased IV Fluids
Surgical instruments	• Consider several of each instrument set above • Craniotomy set • Several external fixator sets • Surgical suction and tubing • Surgical energy device (e.g., Bovie)
Other surgical equipment	• Consider larger capacity blood refrigeration equipment • Litters • More than 1 OR Table/Litter Stands + Arm Boards • Overhead Free-standing Lighting • Plasma thawer or Belmont Rapid Infuser • Instrument sterilizer • More robust MASCAL kit • Additional litters
Electronics	• Arterial line pressure monitoring equipment
Operational equipment	• Larger generator(s) with required fuel, wiring, circuit panels • Multiple space heaters • Wall mounted lighting

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Blunt Abdominal Trauma, Splenectomy, and Post-Splenectomy Vaccination (CPG ID:09)

To provide guidance on the management of combat casualties who sustain blunt abdominal trauma.

JTS CPGs are developed and peer reviewed by subject matter experts serving on the Defense Committees on Trauma: the Committee on Tactical Combat Casualty Care; the Committee of Surgical Combat Casualty Care; and the Committee of En Route Combat Casualty Care. Special thanks goes to these individuals who donate their time and share their experience to aid the JTS mission of publishing standardized clinical practice guidelines which improve patient care and save lives.

BACKGROUND

Unlike penetrating abdominal injuries where the decision to operate is relatively straight forward, those combat casualties that sustain Blunt Abdominal Trauma (BAT) offer more of a diagnostic and clinical challenge. With the improvements in body armor, truncal injury has decreased despite increasingly more lethal weapon systems. With the advent of Improvised Explosive Devices (IEDs), however, more casualties are presenting with evidence of BAT. While Computed Tomography (CT) scans are available to assist the provider in decision making at a Role 3 facility, providers at far forward surgical units must decide to operate based on a physical and a focused assessment with sonography for trauma (FAST) exam.[1]

It is incumbent on the senior surgeon at each facility to ensure the staff understands their resource limitations and the inherent limitations associated with the use of the FAST exam to diagnose a hemoperitoneum. For hemodynamically unstable trauma patients with a positive FAST, exploratory laparotomy should be undertaken immediately. Rarely, patients with a positive FAST and/or CT scan may be managed non-operatively if they are already at a Role 3 facility that can ensure adequate clinical follow-up and evaluation. Patients who have a positive FAST exam and/or evidence of hemoperitoneum through CT at a surgical facility should not be transferred until any and all ongoing intra-abdominal hemorrhage is completely assessed and controlled. The benefits of non-operative management do not outweigh the risks of an in-flight hemorrhagic emergency with no potential for therapeutic surgical intervention. Patients who evolve peritonitis by physical exam or continue to consume blood products in order to maintain blood pressure warrant exploratory laparotomy. An algorithmic approach to the blunt trauma patient is presented in Appendix A.

Splenic injury grading is presented in Table 1 below. All grade IV-V splenic injuries should undergo splenectomy due to the high risk of failure of non-operative management with or without splenic embolization[2] and the need for prolonged transportation out of theater. Lacerated spleens of any grade with active hemorrhage encountered during laparotomy for any reason are best managed by splenectomy. If the tactical situation permits stable grade III splenic injuries without active extravasation, pseudo aneurysm, hemoperitoneum on CT scan or other indications for laparotomy that may include, but are not limited to associated injury may undergo attempt of non-operative management under the direct supervision of an experienced trauma surgeon.[3] Ideally, patients undergoing attempted splenic salvage should be monitored in the Role 3 facility for at least 48 hours prior to strategic evacuation out of theater. In Role 3 facilities with interventional radiology capabilities, embolization of grade III splenic injuries may be considered as an adjunct to non-operative management. Embolization is not definitive treatment for splenic injuries so these patients must also be monitored for 48 hours following the procedure and prior to strategic aeromedical evacuation from theater.

Table 1. Organ Injury Scaling Spleen

Grade	Injury Description	AIS 90
I	Subcapsular Haematoma, <10% surface area Laceration Capsular tear, <1cm parenchymal depth	2 2
II	Subcapsular Haematoma, 10-50% surface area Intraparenchymal, <5cm diameter Laceration 1-3cm parenchymal depth not involving a parenchymal vessel	2 2
III	Subcapsular Haematoma, >50% surface area or expanding. Ruptured subcapsular or parenchymal haematoma. Intraparenchymal haematoma >5cm Laceration >3cm parenchymal depth or involving trabecular vessels	3 3
IV	Laceration of segmental or hilar vessels producing major devascularization (>25% of spleen)	4
IV	Laceration Completely shattered spleen Vascular Hilar Vascular Injury which devascularized spleen	5 5
	Advance one grade for multiple injuries to same organ up to Grade III.	

A contrast CT scan should be obtained at 48 hours (and before aeromedical evacuation out of the Role 3 to assess for complications such as pseudonaneurysm formation on all patients undergoing non-operative management of splenic injury.[4] Indicators of failure of non-operative management of the spleen include but are not limited to any need for blood transfusion and any hypotensive episode. For Grade I-III splenic injuries success rate of non-operative management with embolization reach 99-100%. Patients who fail non-operative management of the spleen require splenectomy at the Role 3 prior to aeromedical evacuation. It must be stressed that placing a patient in the aeromedical environment is akin to discharge from the facility ***without activity restriction*** and without the option of re-admission during the complete inter-facility transport between theaters which must be assumed to be a minimum of 12 hours. Additionally, the patient's history should be discussed between the referring and accepting surgeons prior to evacuation. Patients with Grade III splenic injury and Traumatic Brain Injury (TBI) should undergo splenectomy due to the fact that hypotension with TBI will double mortality.[5] Angiography and embolization for blunt injuries of other visceral organs may be used as an adjunctive procedure and should be determined on a case by case basis.

OVERWHELMING POSTSPLENECTOMY SEVERE INFECTION (OPSI)

In a review of post-splenectomy patients from 1966-96, with a median follow-up of 6.9 years, invasive infection occurred in 2.3% of trauma patients with a 49% mortality rate.[6] Patients present with nonspecific flu-like symptoms rapidly progressing to fulminant sepsis, consumptive coagulopathy, bacteremia, and untimely death within 12-48 hours. The infections are typically caused by encapsulated organisms including Streptococcus pneumoniae, Haemophilus Influenzae type B, and Neisseria meningitidis, for which there are effective vaccines. One study demonstrated that only 56.7% of patients receive all vaccines needed.[7] Since these patients are at risk for OPSI, there must be a standardized process to provide post-splenectomy vaccination, accurate documentation, and life-long tracking to identify outcomes.

VACCINE CANDIDATES

All splenectomized patients and those deemed to be functionally asplenic (e.g., <51% normal architecture and/or vascularization in the remaining splenic segment).

VACCINE DOSING

PNEUMOCOCCAL

1. Prevnar 13 (PCV13) AND Pneumovax 23 (PPSV23) are both recommended.[8]
2. Single dose of PCV13 should be given to patients who have not previous received PCV13.
3. PPSV23 should be given 8 weeks after PCV13 for those who have not previously received PPSV23.
4. One-time revaccination of PPSV23 should be administered 5 years after the first dose.

HAEMOPHILUS INFLUENZAE TYPE B (HIB)

Single dose of any Hib conjugate vaccine (PedvaxHIB, ActHIB, or Hiberix) is recommended for those who have not previously been vaccinated for Hib.[9]

MENINGOCOCCAL

1. Vaccination for serogroup B (MenB) as well as serogroups A, C, W, and Y (MenACWY) is recommended.[10,11,12]
2. For those not previously vaccinated for MenB, either Bexsero (2 dose series) or Trumenba (3 dose series) may be given.
3. For those not previously vaccinated for MenACWY, either Menveo or Menactra should be administered as a 2 dose primary series. After the primary series, a booster dose is recommended every 5 years.
4. For those that have been vaccinated for MenACWY within 5 years, no booster is needed. If vaccinated beyond 5 years, a booster dose should be administered.
5. If Menactra is the only MenACWY vaccine available and the patient also is recommended to get Prevnar 13, Menactra should be administered 4 weeks after Prevnar 13.

VACCINATION ADMINISTRATION TIME

All patients for Aeromedical Evacuation: Administer recommended vaccines in the immediate postoperative period at the first facility that can do so. See above for timing if patient is recommended for both Prevnar 13 and Menactra. Role 3 and Role 4 facilities should not assume that vaccination have occurred prior to arrival.

Host nation and other patients NOT evacuated out of theater: Administer recommended vaccines in the immediate postoperative period at the first available opportunity but no later than the 14th postoperative day.

Table 2. Guide for the Vaccine Naïve Patient

Guide for the Vaccine Naïve Patient (*If patient has previously received one or more of the listed vaccines, see text for guidance.*)				
Bacteria	**Vaccine**	**Dose and Timing***		
Streptococcus pneumoniae	Prevnar 13	Single Dose		
	Pneumovax 23	One dose ≥8 weeks after Prevnar 13	Second dose 5 years after first dose	
Nesseria meningitidis	Bexsero or Trumemba (serogroup B)	Dose #1	Dose #2 one month after first dose	If using Trumemba, Dose #3 five months after Dose #2
	Menactra or Menveo (serogroups A, C, W, and Y)	Dose #1 (if using Menactra, give 4 weeks after Prevnar 13®)	Dose #2 one month after first dose	Booster dose given every 5 year interval
Haemophilus influenza type b	PedvaxHIB **or** ActHIB **or** Hiberix	Single Dose		

**Vaccines should be administered as soon as the patient is clinically stable post-operatively*

VACCINATION DOCUMENTATION

A dated, timed, and signed physician order for recommended vaccines will be documented on the physician order form. If any recommended vaccines are not ordered, there must be clear documentation indicating the rationale for why one or more vaccines were not ordered. Doing so will facilitate clear communication along the continuum of care.

Vaccine administration documentation on the medication administration record (MAR) will include date, time, dose, lot number/lot sticker, manufacturer, and nurse signature for each vaccine. If any or all of the vaccines are ordered, but not administered (for any reason), the ordering physician must be notified, and there must be clear documentation indicating this and the rationale for why one/more vaccines were not administered. Also, document which provider was notified. This facilitates clear communication along the continuum of care.

Documentation in the electronic medical record for the physician order, dispensing from the pharmacy or immunization clinic, and nursing administration is preferred when possible. Documentation of vaccination is highly recommended in the service specific vaccination tracking systems (MEDPROS for Army, MRRS for Navy/Marine/Coast Guard, and ASIMS for Air Force) if available at the treating facility or operating base.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All trauma patients with blunt trauma injury type ***and*** any AIS-abdominal code.

INTENT (EXPECTED OUTCOMES)

1. Hemodynamically unstable (SBP < 90) blunt trauma patients with positive FAST undergo laparotomy (unless documented reason to delay/avoid).

2. All patients with grade IV and V splenic injuries requiring long-range evacuation undergo splenectomy or reason for non-operative management is documented.

3. Selective non-operative management of hemodynamically stable Grade I-III blunt splenic injury is performed at Role 2E, 3 or 4.

4. All patients who undergo splenectomy receive splenectomy vaccinations.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in population of interest with SBP <90 and positive FAST on arrival to a surgical capability who undergo exploratory laparotomy at the same level of care.

2. Number and percentage of patients with grade IV and V splenic injuries who undergo splenectomy.

3. Number and percentage of patients with each grade of splenic injury who are managed non-operatively.

4. Number and percentage of patients who undergo splenectomy who have documentation of pneumococcal and **HAEMOPHILUS** influenza vaccines.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Director, JTS Program Manager, and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

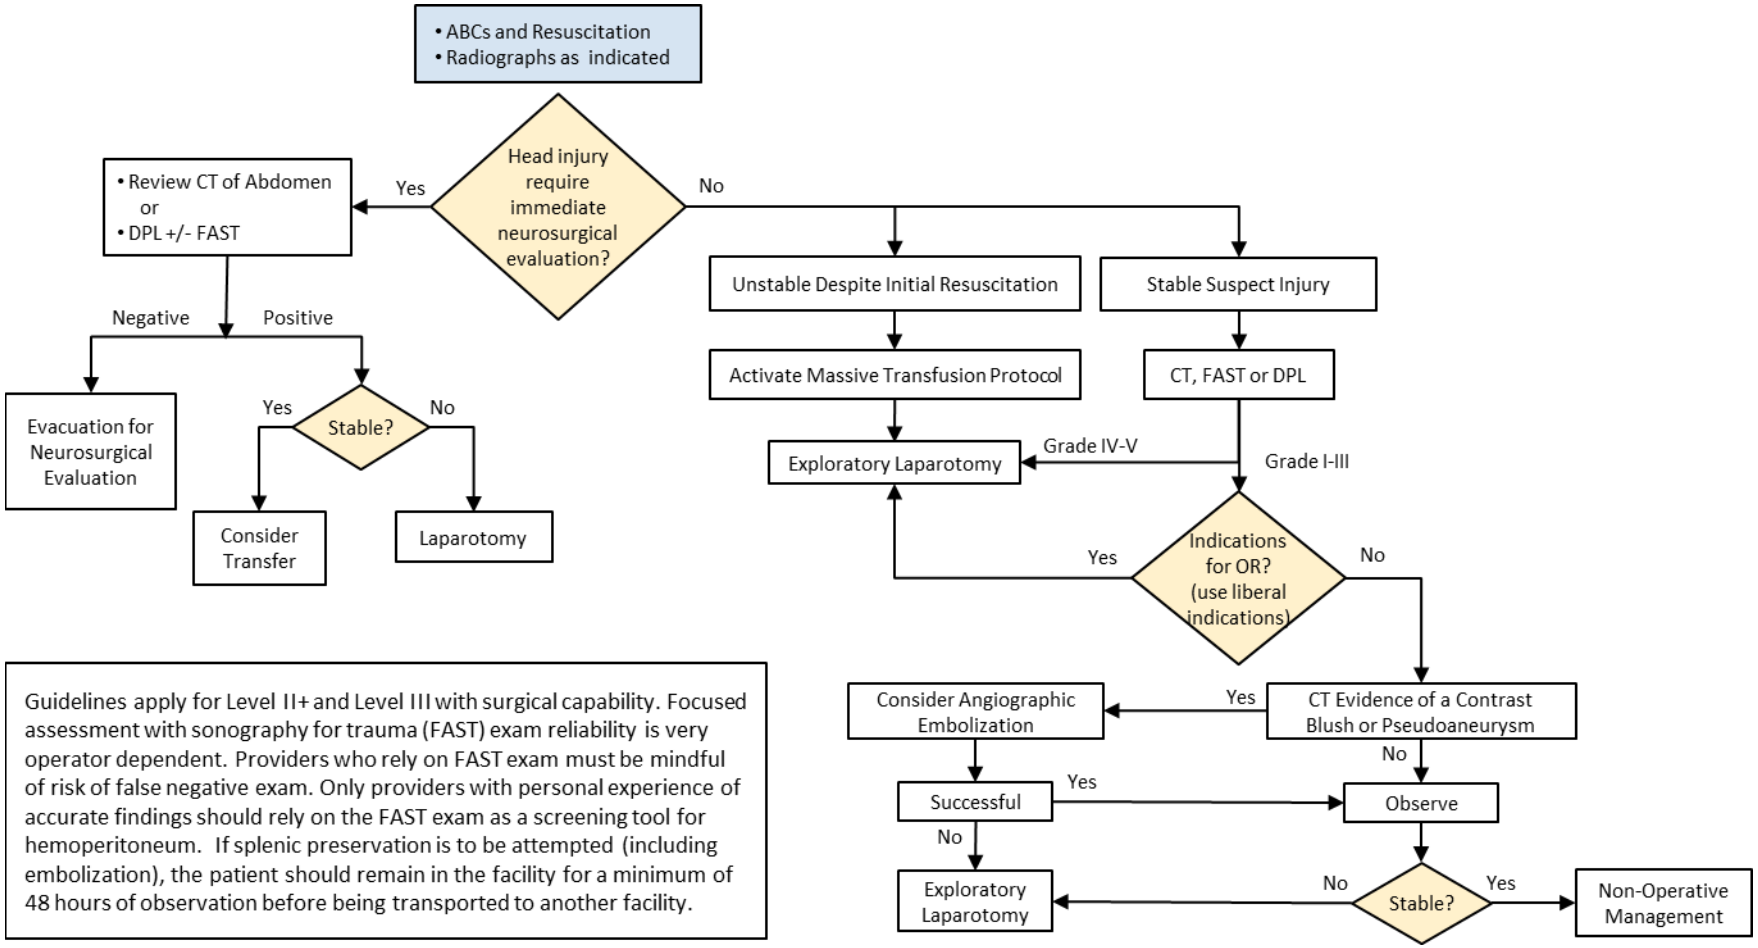
APPENDIX A: ALGORITHM FOR EVALUATING BLUNT ABDOMINAL TRAUMA



Guidelines apply for Level II+ and Level III with surgical capability. Focused assessment with sonography for trauma (FAST) exam reliability is very operator dependent. Providers who rely on FAST exam must be mindful of risk of false negative exam. Only providers with personal experience of accurate findings should rely on the FAST exam as a screening tool for hemoperitoneum. If splenic preservation is to be attempted (including embolization), the patient should remain in the facility for a minimum of 48 hours of observation before being transported to another facility.

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (CPG)

Burn Care (CPG ID: 12)

Addresses burn injury assessment, resuscitation, wound care, and specific scenarios including chemical and electrical injuries. Reviews considerations for the definitive care of local national patients, including pediatric patients, who are unable to be evacuated from theater.

INTRODUCTION

The goal of this CPG is to provide practical, evidence-based recommendations for optimal care of burn casualties in the deployed or austere setting who generally fall into one of two categories: military casualties who can be evacuated out of theater for definitive care and local national patients, often children, who are presented for care at military medical facilities with no possibility of definitive care beyond that provided in theater.

> ***NOTE:*** *If caring for a burn casualty, contact the U.S. Army Institute of Surgical Research (USAISR) Burn Center as soon as possible. Early consultation will facilitate coordination of care to include possible activation of the Burn Flight Team to assist with movement back to Continental U.S. (CONUS). Inability to contact the Burn Center should not delay the evacuation process. Contact the Joint Patient Movement Requirements Center (JPMRC) as soon as possible to coordinate aeromedical evacuation.*
>
> ***Burn Center***
>
> - *DSN 312-429-2876 (429-BURN)*
> - *Commercial (210) 916-2876 or (210) 222-2876*
> - *Email to usarmy.jbsa.medcom-aisr.list.armyburncenter@health.mil*

Optimal treatment of burn patients can consume enormous personnel and logistical resources. Despite the best efforts of providers at each level of care, the mortality for burn casualties who cannot be evacuated out of theater is significantly higher than that experienced in CONUS facilities. These and other factors must be considered in the deployed environment. Review of *Chapter 26: Burn Trauma in the 2013 Emergency War Surgery* manual is also recommended.[1]

POINT OF INJURY

1. In the field, ***INTERRUPT THE BURNING PROCESS*** and address any life threatening bleeding, airway compromise, or tension pneumothorax as directed by Tactical Combat Casualty Care guidelines. Burn casualties may have additional traumatic injuries which may be more life threatening and require immediate attention.

2. Address any life threatening bleeding, airway compromise, or tension pneumothorax per tactical combat casualty care guidelines.

3. Rinse off dirt and any contaminating chemicals, including hydrocarbon fuels, with clean water. Dry chemicals should be brushed off before irrigation. Once a survey of injuries is performed, cover the patient with blankets to prevent hypothermia.

4. Evacuate the casualty as soon as possible. Tactical considerations and distance may precipitate prolonged field care in which resuscitation is begun under pre-hospital conditions.

INITIAL BURN SURVEY

1. Perform primary and secondary surveys for any trauma patient. Acute injuries found in the primary and secondary survey should be addressed as per standard trauma protocols. Avoid becoming distracted by the appearance of burned tissues.

2. Assess and protect the airway, if needed. Immediate intubation may not be necessary in less severely burned casualties, thereby allowing time to complete the primary survey and prepare for controlled intubation.

3. Indications for endotracheal intubation include a comatose patient, symptomatic inhalation injury, deep facial burns, and burns over 40% Total Body Surface Area (TBSA).

NOTE: *Edema after burn injury causes most Supraglottic airway devices such as laryngeal mask airways (LMAs) to be inadequate.*

4. Use a large-bore endotracheal tube (ETT), especially if inhalation injury is suspected. Size 8 ETT or larger is preferred for adults. The larger ETT tube facilitates subsequent bronchoscopy and pulmonary toilet, and decreases the risk of later airway occlusion due to casts comprised of blood, mucus and debris.

5. Secure ETT with cotton umbilical ties which can be adjusted as edema develops during resuscitation; standard adhesive ETT holders do not work around burned skin. Consider securing ETT with stainless steel wire secured around a pre-molar tooth prior to long-range transport, particularly in patients with extensive facial burns. Frequently reassess position of the ETT during the acute resuscitation period as edema waxes and wanes.

6. Keep the patient warm. Burns increase insensible heat loss. Burn casualties with injuries >20% TBSA are at high risk of hypothermia.

NOTE: *Do not debride blisters until the patient has reached a facility with surgical capability. Cover burns with loose, dry gauze wraps or a clean sheet.*

ACUTE RESUSCITATION

1. Calculate the patient's initial burn size using the Rule of Nines (Appendix A). When wounds are cleaned, re-calculate using the Lund-Browder charts (Appendix B and Appendix C). Superficial (1st degree) burn is NOT included in the estimation of TBSA used for fluid resuscitation.

2. Superficial burns (1st degree) appear red, do not blister, and blanch readily. Partial thickness burns (2nd degree) are moist and sensate, blister, and blanch. Full thickness burns (3rd degree) appear leathery, dry, non-blanching, are insensate, and often contain thrombosed vessels.

3. If TBSA is 20% or greater, patients typically require acute fluid resuscitation for the next 24 to 48 hours with close observation until hour 72 post-burn.

4. Place a Foley catheter with calibrated urometer chamber. Burns to the penis are not a contraindication to urinary catheter placement. Suprapubic bladder catheter placement is rarely, if ever, required in burn patients and should be avoided in the presence of abdominal burns.

5. If available, for patients weighing 40 kg or more, use the Burn Navigator, a burn resuscitation decision support fluid calculator.[2] At the top of every hour, follow the prompts and enter the intake and urine output (UOP) values. The device will provide isotonic fluid rate recommendations for the next hour. For guidance, see the Burn Navigator Training and Resources.

6. The device uses feedback algorithms and the principles listed below to make fluid rate recommendations. The goal is to achieve an hourly target UOP of 30-50mL/hr.

7. Intake and output tables and graphs display how much fluid a patient received. Graph colors change as the patient approaches over-resuscitation danger zones of >200mL/kg and then >250mL/kg.

8. The system seeks to encourage communication between physicians and bedside nurse by displaying an assessment checklist, alert, and minimum and maximum rate recommendations.

9. Each Burn Navigator device allows resuscitation of only one patient at a time.

   CAUTION: *The Burn Navigator is NOT intended to be used for electrical burn injuries resulting in rhabdomyolysis with pigmenturia (red-brown urine). Resuscitation fluid needs in these patients often outpace the system's recommendations. Use clinical judgment and consider the entire scenario when interpreting recommendations, especially when patients have conditions that artificially alter UOP.*

10. For adults, if the Burn Navigator system is not available, initiate manual intravenous (IV) fluid resuscitation using the Rule of 10s (10 mL/hr x %TBSA)[3] Use the Burn Resuscitation Worksheet (Appendix D) [4] to assist initiation of fluid resuscitation.

11. For patients weighing more than 80 kg, add 100 mL/hr to IV fluid rate for each 10 kg >80 kg.

12. For children, 3 x TBSA x body weight in kg gives the volume for the first 24 hrs. One half is programmed for delivery during the first 8 hours. Further guidance for pediatric management is provided below.

13. Lactated Ringer's (LR), PlasmaLyte A (Baxter International, Deerfield, Il) or other isotonic solution is the preferred resuscitation fluid; other solutions (normal saline) should be used with caution as electrolyte imbalances may result. In the absence of overt hypotension (MAP <55), avoid fluid boluses as additional volume contributes to edema. Instead, increase the rate of IV fluids to maintain adequate organ perfusion, as reflected by urine output (UOP).[3]

14. The use of blood products in major burn resuscitation due to coagulopathy, anemia, and bleeding from escharotomy sites or other traumatic injuries is common. Refer to the Joint Trauma System Damage Control CPG for transfusion guidelines and resuscitation of patients with other significant injuries.

15. Monitor UOP closely and decrease or increase the isotonic fluid rate by approximately 20-25% per hour to maintain a UOP of 30-50 mL/hour in adults, or 0.5 to 1 ml/kg /hr in children. Every attempt should be made to minimize fluid administration while maintaining organ perfusion. If UOP> 50 mL/hr, then decrease the fluid rate by 20% for two consecutive hours and reassess. Increase rate of LR by 20% if UOP is less than 30 mL/hr (adults) or pediatric target UOP for 2 consecutive hours. Over-resuscitation can lead to many life threatening complications in the burn patient - so close monitoring of UOP and end organ perfusion is imperative.

16. Both under- and over-resuscitation can result in serious morbidity and even mortality; patients who receive over 250 mL/kg in the first 24 hours are at increased risk for severe complications including acute respiratory distress syndrome and both abdominal and extremity compartment syndromes.

17. Hour-to-hour fluid management is critical, particularly during the first 24 hours. Use the Burn Resuscitation Flow Sheet (Appendix D) to record both fluid intake and UOP.

18. At 8-12 hours post-burn, if the hourly IV fluid rate exceeds 1500 mL/hr or if the projected 24 hr total fluid volume approaches 250 mL/kg, initiate 5% albumin infusion using Table 1 (Adults only); for children, infuse 4-7 mL/kg at the rate of 0.5 mL per minute. Continue the 5% albumin infusion until the 48-hour mark. Fresh frozen plasma may be substituted. In children, consider colloid infusion at calculated maintenance rate, reducing the calculated isotonic infusion by at equal volume.

Table 1: Hourly infusion rates for 5% albumin for adults

5% Albumin Infusion (ml/hr)	30-49%TBSA	50-69% TBSA	70-100% TBSA
<70 kg	30	70	110
70-90 kg	40	80	140
>90 kg	50	90	160

19. If possible, measure bladder pressures every 4 hours in intubated patients with >20% TBSA burns.[5] Ensure the patient is in the supine position and follow the manufacturer's instructions for commercial kits; otherwise, use between 25 and 50 ml, being consistent in whatever volume is used, for serial measurements using a transducer located at the level of the symphysis pubis. Sustained bladder pressure >12 mmHg indicates early intra-abdominal hypertension and adjuncts such as colloid fluid should be considered. If the measured pressure is >20mmHg, the patient should be paralyzed and the measurement repeated. Persistent bladder pressures >20mmHg may indicate abdominal compartment syndrome (See Abdominal Compartment Syndrome below).

20. Combat casualties with burns often present with multi-system injury, to include inhalation injury, hemorrhage, and soft tissue trauma. Associated injuries may increase fluid needs above and beyond standard burn resuscitation formulas.

21. After approximately 24-72 hours, completion of resuscitation is marked by stabilizing hemodynamic parameters and reduction of IV fluid rate to a maintenance level. A well-resuscitated adult burn patient should follow commands, be hemodynamically stable, be tachycardic in the range of 110-130 beats per minute, and have UOP between 30-50 mL/hr. Acid-base balance should normalize, hematocrit should reveal a dilutional anemia, and pulses should be present in all extremities.

MANAGEMENT OF PERSISTENT OLIGURIA AND HYPOTENSION

Clinically significant hypotension must be correlated with UOP. Adequate end organ perfusion as estimated by UOP 30-50 mL/hr generally requires a MAP >55mm Hg. Persistent oliguria and hypotension should trigger an assessment of the patient's hemodynamic status and intravascular volume. Reassess for a possible missed injury or ongoing bleeding. Monitor intravascular fluid status using all available technologies. Consider early use of 5% albumin as discussed above as an adjunct.

When available, monitor central venous pressure (CVP); goal CVP is 6-8 mmHg. If CVP is low, increase IV fluid rate. If CVP is at goal but hypotension (Mean Arterial Pressure, MAP < 55mmHg) persists, use vasopressin 0.04 Units/min (do not titrate) followed by norepinephrine (titrate 2-20mcg/min) if needed. Epinephrine and phenylephrine may be used as additional vasopressors in severe shock proven to be non-hemorrhagic. If intravascular volume appears adequate (CVP at goal), STOP increasing IV fluid rate even if oliguria persists. Consider this patient hemodynamically optimized and that the oliguria likely results from an established renal insult. Expect and tolerate some degree of renal dysfunction in large burns. Continued increases in IV fluid administration, despite optimal hemodynamic parameters, will only result in "resuscitation morbidity," that is often times more detrimental than renal failure.

If the patient exhibits catecholamine-resistant shock, consider the following diagnoses:

- Missed injury and/or on-going blood loss.

- Acidemia. If pH < 7.20, adjust ventilator settings to target PCO2 30-35 mm Hg. If, despite optimal ventilation, patient still has a pH < 7.2, consider administration of sodium bicarbonate or THAM (tris-hydroxymethyl aminomethane).
- Adrenal insufficiency. If suspected start hydrocortisone 100 mg IV every 8 hours. Use of etomidate during rapid sequence intubation may increase risk of adrenal insufficiency.[6]
- Hypocalcemia. Consider empirically administering calcium chloride (8-16mg/kg IV) for refractory hypotension, especially in patients who have received a blood transfusion. If able to measure levels, maintain ionized calcium > 1.1 mmol/L.

SPECIAL CONSIDERATIONS

ANTIMICROBIAL PROPHYLAXIS

1. Prophylactic IV antibiotics are not indicated for burn injury in the absence of infection. Penetrating wounds or open fractures should be treated with antibiotics according to current guidelines. See Wound Care section for discussion of topical antimicrobials.

2. Administer tetanus prophylaxis as for any trauma patient.

3. If wound infection is diagnosed clinically, direct empiric therapy against gram positive and gram negative bacteria based on known geographic susceptibilities. If this data is unavailable, a good starting point is broad coverage with vancomycin for gram positive organisms and a carbapenem or 4th generation cephalosporin for gram negative organisms.

INHALATION INJURY

NOTE: *Refer to the JTS Inhalation Injury and Toxic Industrial Chemical Exposure CPG for additional information* [4]

1. Inhalation injury occurs secondary to smoke exposure and is exacerbated by retained carbonaceous particles (soot) and chemicals. Clinical signs include progressive voice changes, soot about the mouth and nares, hypoxia, and shortness of breath (See Initial Burn Survey for airway management recommendations). If available, use bronchoscopic lavage to remove debris. Be judicious, as excessive irrigation may transport irritants to uninjured lung. Serial bronchoscopy may be required to remove large debris or casts. Patients diagnosed with inhalation injury should receive aerosolized unfractionated heparin 5000 units per ETT every 4 hours; mix heparin with albuterol, as heparin can induce bronchospasm.

2. Populations at risk for carbon monoxide (CO) toxicity include those exposed in enclosed spaces to fires, engines, and cooking stoves. Symptoms of CO toxicity include confusion, stupor, coma, seizures, and cardiac ischemia. Administer 100% oxygen and measure CO-hemoglobin levels via co-oximetry if available. Hyperbaric oxygen therapy may further reduce the CO-hemoglobin half-life but this therapy is cumbersome and not available while deployed.

3. Cyanide is encountered in fires and industrial processes. Early effects include dizziness, headache, nausea, and anxiety. High dose exposure causes rapid onset of coma, seizure, respiratory depression, hypotension, and tachycardia. Lactic acidosis > 8 mmol/L is common. Administer 100% oxygen via mechanical ventilation. Hydroxocobalamin is the preferred antidote; infuse 5 grams IV over 7 minutes. It may be infused over 2-5 minutes in cases of cardiac arrest or severe hypotension, and may be repeated

if no clinical improvement.[4] Cyanokit™ should be available at every Role 3 hospital and Role 2 hospitals as well if there is a high risk of managing burn casualties.

4. Hydrogen fluoride (HF) is a byproduct of standard fire suppression systems. Exposure to HF may result in rapidly progressive or fatal respiratory failure despite minimal external evidence of injury. Symptoms include shortness of breath, cough, or hypoxia; there must be a high level of suspicion for HF inhalation.[9] Treatment is supportive. If hypocalcemia is present, administer nebulized calcium gluconate (1.5 ml of 10% calcium gluconate in 4.5 ml water) q4hr until normalization of serum calcium levels. In the absence of significant burns, consider steroids if symptoms do not improve. Bronchopneumonia can develop within a week.

OPHTHALMIC INJURY

NOTE: *Refer to the JTS Eye Trauma: Initial Care CPG for additional information.*[4]

1. Every patient with facial burns should have a thorough eye exam. If available, consult an ophthalmologist for all patients with facial burns or corneal injury verified by Wood's lamp exam. Eye exams should be done early, before facial edema sets in.

2. If no injury exists, lubricate the eyes of intubated patients every 2 hours with lacrilube.

3. If a corneal injury is identified, use a Fox shield to cover the eyes and apply ophthalmic erythromycin ointment at least every 2 hours.

4. If there is suspicion of an open globe injury, no drops or ointment should be applied, place a Fox eye shield and refer to an ophthalmologist as soon as possible. For further details, please refer to the Joint Trauma System Ocular Trauma CPG.[4]

LINES AND TUBES

1. Sew and/or staple all venous and arterial catheters in place as tape does not adhere to burned skin. Do not circumferentially tape lines around extremities; this may further impede circulation and cause limb ischemia as extremities swell during resuscitation.

2. Use umbilical ties to secure endotracheal, orogastric, nasogastric and Dobhoff tubes.

GASTROINTESTINAL PROPHYLAXIS

1. Burn patients, regardless of age, are prone to nausea and vomiting as well as stress ulceration.

2. Place orogastric or nasogastric tube in all intubated patients for gastric decompression during resuscitation and later for enteral nutrition.

3. Administer IV proton pump inhibitor or similar agent to all patients with >20% TBSA burn injury.

CIRCUMFERENTIAL BURNS, ESCHAROTOMY, AND EXTREMITY COMPARTMENT SYNDROME

1. Escharotomy is normally performed in the setting of a circumferential full thickness burn. If the burn is superficial or not circumferential and pulses are absent, first rule out hypovolemia, hypotension, or occult bleeding. Escharotomy incises the skin but not the fascia, and is usually sufficient for

compartment syndrome caused by burns unless there is underlying muscle damage or over resuscitation. Refer to the Escharotomy Chart in Appendix E.

2. The requirement for escharotomy or fasciotomy usually presents in the first 6-24 hours following injury. If the need for either procedure has not been identified within the first 24-48 hours, then circulation is likely to remain adequate without surgical intervention. Elevation of the burned extremities 30-45° is required to decrease edema. A patient who required escharotomy or fasciotomy at a lower echelon of care should always have their extremity compartments reassessed upon arrival at the next echelon of care. Extension of the incision(s) may be required to restore circulation. This situation can occur if large IV fluid volumes are given during transport, compounding tissue edema. The threshold for escharotomy should be low in patients requiring transportation, but must take into account the ability to transfuse the patient after the procedure.

3. For any circumferential extremity (including fingers) burn, hourly monitoring is essential. The extremity should be elevated as high as feasible, especially during transport. Palpable radial pulses do not exclude digital compartment syndrome and digital pulses must be checked by using the Doppler to assess the palmar arch and digital arteries for hand and digit burns. In general, palpable pulses of the radial, dorsalis pedis and posterior tibialis is sufficient as long as there are no burns distal to these pulses. Absent Doppler signals or pulses that are diminishing on hourly exams should prompt immediate consultation with a burn surgeon and strong consideration of surgical decompression with escharotomies.

4. Repeat the vascular exam at least every hour. If available, use handheld Doppler ultrasound to assess the palmar arch, dorsalis pedis, and posterior tibialis. A triphasic signal in the above vessels is considered normal. Consider performing escharotomy early, based upon the vascular exam. Consider fasciotomy in the operating room if pulses remain undetectable even after escharotomy. Continue hourly pulse checks to ensure adequate perfusion following surgical decompression.

5. Escharotomy is performed by incising full thickness burns into the subcutaneous fat. Patients will require analgesia, sedation, and usually intubation. Because escharotomy can be associated with significant blood loss, at times it may be more prudent to rapidly evacuate the patient to a higher echelon of care rather than initiate the procedure in an austere environment. This is a judgment call based upon assessment of local resources and transportation time and availability.

6. Using electrocautery to perform escharotomy reduces bleeding compared to a scalpel. Extend escharotomy incisions the entire length of the circumferential portion of full-thickness burn. The depth of the incision should be through the dermis to the level of subcutaneous fat; it is not necessary to carry the incision to the level of fascia. Carry incisions across involved joints. Although full thickness burn is insensate, patients will require IV narcotics and benzodiazepines during this procedure. On completion of the escharotomy, reassess perfusion. If circulation is restored, bleeding should be controlled with electrocautery and the extremity dressed and elevated at a 30-45° angle. Assess pulses hourly for at least 12-24 hours.

7. Thoracic escharotomy incisions should extend from the neck, across the mid-clavicle, and down the anterior axillary line. Connect each side with an incision across the upper abdomen.

8. In the upper extremities, place the hand in the anatomic position (palm facing forward) and make an incision in the mid radial or mid ulnar line, carrying the incision up the arm. Ulnar incisions should stay anterior (volar) of the elbow joint to avoid the ulnar nerve, which is superficial at the level of the elbow. If both hand and arm are burned, continue the incision across the mid ulnar or mid radial wrist and onto the hand. If circulation is not restored, perform a second incision on the opposite side of the extremity.

9. If finger escharotomies are required, avoid functional surfaces (radial surface of the index finger and ulnar surface of the little finger). Place the fingers in a clenched position and note the finger creases at DIP and PIP joints. Escharotomy incisions should be just dorsal to a line drawn between the tops of these creases.

10. Lower extremity escharotomy incisions are placed in the mid-lateral and/or mid-medial line extending from the ankle to the hip. If circulation is not restored, perform a second incision on the opposite side of the extremity.

11. If bilateral extremity escharotomy incisions do not restore circulation, re-evaluate the adequacy of the patient's overall hemodynamic status. Re-assess for a possible missed injury or ongoing bleeding.

12. Consider fasciotomy in the operating room (OR) if pulses remain undetectable after escharotomy. Continue hourly exams to ensure adequate perfusion following interventions. Optimal fluid resuscitation and prompt escharotomy usually mitigates the need for fasciotomy. Due to the frequency of extremity injuries seen among combat casualties, fasciotomies on burned extremities may be required for those with delayed revascularization, hemorrhage requiring massive resuscitation, and crush injuries. For further details, see the JTS Acute Extremity Compartment Syndrome and the Role of Fasciotomy in Extremity War Wounds CPG.[4]

13. High altitude aeromedical evacuation is not, in and of itself, a contributor to the development of compartment syndrome in a burned extremity. Escharotomy/fasciotomy for thermal burns should only be performed for the clinical diagnosis of compartment syndrome, and if available, confirmed by measurement of compartment pressures.

14. Following escharotomy or fasciotomy, late bleeding may occur as circulation is restored. Examine the surgical site every few minutes for up to 30 minutes for signs of new bleeding, which is usually easily controlled with electrocautery.

ABDOMINAL COMPARTMENT SYNDROME

Massive fluid replacement (> 250 mL/kg within 24 hours) is a risk factor for abdominal compartment syndrome, a clinical diagnosis which includes increased bladder pressure, increased airway pressures, oliguria, and hypotension.[7,8] Bladder pressure > 20 mm Hg in the setting of this syndrome warrants early consideration of therapeutic paracentesis which may provide partial relief of elevated intra-abdominal pressure related to sequestration of resuscitation fluid in burn patients.

The decision to pursue decompressive laparotomy must factor in the significant risk of morbidity and mortality from the procedure in patients with extensive burns or burns to the abdominal wall.[7] If the patient requires a decompressive laparotomy, perform a standard celiotomy followed by a temporary abdominal closure. If the abdominal wall skin is burned, adhesive drapes for negative pressure wound dressings (NPWD) will not adhere to the skin edges. Use of a Bogotá bag or similar sterile plastic material sewn to the skin edges is preferred.

CHEMICAL BURNS

NOTE: *Refer to the JTS Inhalation Injury and Toxic Industrial Chemical Exposure CPG for additional information*[4]

1. Expose body surfaces, brush off dry chemicals, and copiously irrigate with clean water. Large volume (>20L) serial irrigations may be needed to thoroughly cleanse the skin of residual agents. Do not attempt to neutralize any chemicals on the skin. Use personal protective equipment to minimize

exposure of medical personnel to chemical agents. Resuscitation strategy and goals for patients with chemical burns are the same as for thermal injuries.

2. White phosphorous fragments ignite when exposed to air. Clothing may contain white phosphorous residue and should be removed. Fragments embedded in the skin and soft tissue should be irrigated out if possible or kept covered with soaking wet saline dressings or hydrogels. Urgently retrieve deeply embedded fragments in the OR. Monitor calcium levels closely and treat hypocalcemia with IV replacement.

3. Contact the Army Burn Center DSN 312-429-2876 (BURN) or (210) 916-2876 or (210) 222-2876 or Email to usarmy.jbsa.medcom-aisr.list.armyburncenter@health.mil.

ELECTRICAL INJURY

1. First responders should remove the patient from the electricity source while avoiding injury themselves.

2. In cases of cardiac arrest due to arrhythmia after electrical injury, follow advanced cardiac life support (ACLS) protocol and provide hemodynamic monitoring if spontaneous circulation returns.

3. Small skin contact points (cutaneous burns) can hide extensive soft tissue damage. Observe the patient closely for clinical signs of compartment syndrome (refer to the Circumferential Burns section above, and the Extremity Compartment Syndrome CPG3 for discussion of escharotomy/fasciotomy). Tissue that is obviously necrotic must be surgically debrided. Note that escharotomy, which relieves the tourniquet effect of circumferential burns, will not necessarily relieve elevated muscle compartment pressure due to myonecrosis associated with electrical injury; therefore fasciotomy is usually required.

4. Compartment syndrome and muscle injury may lead to rhabdomyolysis, causing pigmenturia and renal injury. Pigmenturia typically presents as red-brown urine. In patients with pigmenturia, fluid resuscitation requirements are much higher than those predicted for a similar-sized thermal burn. Isotonic fluid infusion should be adjusted to maintain UOP 75-100 mL/hr in adult patients with pigmenturia. If the pigmenturia does not clear after several hours of resuscitation consider IV infusion of mannitol, 12.5 g per liter of lactated Ringer's solution, and/or sodium bicarbonate (150 mEq/L in D5W). These infusions may be given empirically; it is not necessary to monitor urinary pH. In patients receiving mannitol (an osmotic diuretic), close monitoring of intravascular status via CVP and other parameters is required.

WOUND CARE

Significant personnel and supply resources are required for wound care of major burns. Consideration should be given to rapidly transferring a patient to a higher echelon of care utilizing dry dressings and hypothermia protection at the Role 1 or Role 2 levels. Bear in mind that any dressings will likely be immediately removed upon arrival at the next echelon of care to facilitate patient evaluation.

Whenever possible, debride (remove sloughed skin and blisters) burn wounds in the operating room (OR), thereby providing a clean, warm environment to both examine the wounds and place sterile dressings. Use chlorhexidine gluconate or similar antiseptic cleanser. Debridement may be facilitated by scrub brushes and/or gauze sponges. Definitive removal of burn eschar (sharp/surgical excision) will be performed after stabilization and transport to the USAISR Burn Center.

1. Shave and debride the face, covering wounds with topical antibiotic ointment QID. Ear burns are prone to chondritis; apply mafenide acetate (Sulfamylon®) cream twice a day if available. Avoid pressure from endotracheal tube ties.

   If mafenide acetate (Sulfamylon) is not available prior to or during transport, thoroughly clean twice a day and utilize silver sulfadiazine cream or any other topical antimicrobial ointment. Examine frequently for cellulitis advancing beyond the ear or for evidence of necrosis of the cartilage. This requires surgical debridement.

2. Wrap burns on the scalp, trunk, neck, and extremities in sterile gauze soaked with a 5% solution of Sulfamylon. Apply the solution QID and as needed to keep dressings lightly moist, but not so wet as to cause maceration.

3. Alternatively, burns may be dressed with silver-impregnated nylon, covered with sterile gauze and moistened with sterile water. One of the advantages of this type of burn dressing is the ability to leave the dressing in place for extended periods of time (up to 7 days) which is advantageous during delayed or long-distance evacuations.

4. Avoid over-wetting dressings to avoid maceration of tissues. Frequent assessment of the patient's temperature is necessary to prevent hypothermia secondary to wet dressings, especially during air evacuation.

5. In patients who cannot be safely evacuated for burn excision, consider using silver sulfadiazine cream alternated BID with mafenide acetate (Sulfamylon) cream to provide antimicrobial penetration of thick burn eschar as a bridge to surgical care.

GUIDELINES FOR PATIENTS WHO CANNOT BE EVACUATED FROM THEATER

Care provided in theater is not envisioned to be definitive care. Definitive care for US service members is provided at the USAISR Burn Center in San Antonio, Texas. Coalition forces progress along the evacuation chain in order to return to their home nation health care facilities. Unfortunately, the care available to local national patients may fail to compare to the definitive care available for US and coalition forces. Care decisions are to be made in the context of the available continuum of care for the patient in their nations of origin.

1. Calculate burn size using a Lund and Browder chart (Appendix B and Appendix C.) Triage of local national casualties to an expectant category may be required if their burns exceed the host nation's ability to treat and rehabilitate (e.g. full thickness burns >50% TBSA). If caring for expectant casualties, provide adequate comfort care measures. Take into consideration inhalation injury, medical co-morbidities, and extremes of age, which can increase mortality.

2. For patients with combined partial and full thickness burns of 50% TBSA or greater, with less than half of the burn being full thickness, initiate resuscitation and allow the partial thickness component to declare itself as it is sometimes difficult to determine the full extent of the full thickness burn at the time of initial presentation. After approximately 48-72 hours, reassess the patient to estimate the percentage of full thickness burn more accurately.

3. Consider inhalation injury in relationship to the TBSA burned when deciding whether to classify the patient as expectant; a patient with a 40% TBSA burn and inhalation injury will likely not do as well as a patient with a 40% TBSA burn without inhalation injury.

4. Burn injuries may initially appear survivable, but skin graft loss, infections, or conversion of donor site(s) to full thickness wounds themselves may transform a potentially survivable injury into a fatal one. Be aware of this possibility and the potential change to an expectant category.

5. The transition from aggressive care to comfort care is a difficult decision, especially when the care team has worked exhaustively to maximize survival. The attending surgeon should elicit objective input from medical colleagues, nurses, and facility leadership in making the decision to transition to comfort care as it will solidify the process and assist with closure, especially for those engaged in the care of the patient for extended periods.

6. For patients with a less than 50% TBSA burn, proceed with resuscitation and plan for early excision and grafting within a week to maximize chance of survival.

7. Skin substitutes such as allograft (deceased donor skin) and biologic dressings such as xenograft (pig skin) are not readily available outside CONUS. The extent of burn excision should be guided by the amount of autograft (split thickness donor skin) available. Do not excise wounds if autograft is not available. Tangential excision should be employed, if possible, to preserve viable dermis and subcutaneous fat. The non-viable dermis is excised to healthy, punctate bleeding dermis. Fascial excision is reserved for subdermal burns that extend well into the subcutaneous tissue, and for those burns which are heavily colonized or infected.

8. If patients arrive with open burn wounds, surgically excise to a healthy wound bed and apply negative pressure wound dressing (NPWD) until granulation tissue is noted. If NPWD is not available, apply gauze dressings moistened with an antimicrobial solution such as 5% mafenide acetate (Sulfamylon) until further surgical debridement can occur.

9. Meshing of split thickness skin grafts will maximize available donor skin. Rarely is there a need to mesh skin wider than 2:1; meshing wider than 3:1 is not recommended due to poor outcomes without comprehensive long term rehabilitation outside of a burn center.

10. Utilize dilute epinephrine solution (1:1,000,000 concentration) to infiltrate subcutaneous tissue by clysis prior to harvesting of donor skin with dermatome. This process will minimize blood loss at the donor site(s). Likewise, dilute epinephrine solution provides topical hemostasis during excision of burns. To control raw surface area bleeding apply a non-adherent dressing (e.g., Telfa), followed by a lap pad soaked in the dilute epinephrine solution.

11. Take the patient to the OR for staged excisions and grafting of the full thickness burns with a goal of complete excision within one week of injury. Consider using a NPWD over fresh autograft with intervening non-adherent layer (e.g. Dermanet or negative pressure Silverlon). If NPWD is not available, sew a bulky bolster dressing over the graft site using a non-adherent layer or silver nylon against the split thickness graft. Leave the post-operative dressing in place for 3-5 days.

12. Following NPWD removal, use Sulfamylon moistened gauze dressings for approximately 5-7 days. When graft interstices are closed transition to a topical agent such as Bacitracin or polymicrobial ointment.

13. Whenever resources are available, perform extensive dressing changes in the OR (not ICU or ward), especially early in the treatment process when wounds remain open. This allows for optimal pain control (with airway protection as needed), improves inspection of wounds, and provides a clean and warm environment.

14. Gram negative bacterial and fungal colonization followed by infection is associated with a high rate of graft loss and increases mortality. Liberal use of dilute Dakin's solution (1/4 strength or 0.125% sodium

hypochlorite) to cleanse colonized burn wounds is recommended. Delay grafting procedures until colonization and infection are controlled.

15. Once the grafts are healed, continue to keep patient clean, using showers when available.

16. Early ambulation and physical therapy, is critical to the long-term functional outcome in burn patients. Once post-operative dressings are removed, perform range of motion of all affected joints.

17. Early and continuous nutrition is vital to wound healing. Even patients who are able to eat may need supplementation to meet calorie goals. Provide approximately 35kcal/kg/day to burned adults. Consult a nutritionist when available. Use a nasoenteric feeding tube to provide a high protein, low fat enteral formula and administer a daily multivitamin.

ADDITIONAL CONSIDERATIONS FOR PEDIATRIC BURN PATIENTS

Deployed surgical teams frequently provide initial care for injured local national children. Burn care for children generally follows adult recommendations, with a few modifications as itemized below.[9] See Appendix C: Pediatric Lund Browder Burn Estimate and Diagram.

Airway patency can be lost early in small children with facial or extensive burns as modest mucosal edema can quickly compromise their small airway; carefully securing the ETT with umbilical tie and adequate sedation is important to prevent unplanned extubation.

Peripheral or intraosseous vascular access may suffice initially, but central venous access is more reliable during formal burn resuscitation; catheters should be sewn in place.

Children with burns under 15% TBSA usually do not need a calculated resuscitation. They can be given 1.5x calculated maintenance rate (see 4-2-1 Rule below[9]) and have diapers weighed for urine output. If they can eat, they should be allowed access to bottle feeds. Some of these children can be supported enterally, with nasoenteric infusions of World Health Organization (WHO) resuscitation formula (1L clean water, 8 tsp sugar, ½ tsp salt, and ½ tsp baking soda).[10]

1. Children with acute burns over 15% of the body surface usually require a calculated resuscitation. Place a bladder catheter (size 6 Fr for infants and 8 Fr for most small children). The Modified Brooke formula (3 mL/kg/%TBSA LR or other isotonic fluid divided over 24 hours, with one-half given during the first 8 hours) is a reasonable starting point. This only provides a starting point for resuscitation, which must be adjusted based on UOP and other indicators of organ perfusion. Goal UOP for children is 0.5-1mL/kg/hr. Decrease or increase the isotonic fluid rate by approximately 20-25% per hour to maintain UOP at 0.5-1mL/kg/hr.

2. Very young children do not have adequate glycogen stores to sustain themselves during resuscitation. Administer a maintenance rate of D5LR to children weighing < 20 kg. Utilize the 4-2-1 rule: 4ml/kg for the first 10kg + 2ml/kg 2nd 10kg + 1ml/kg over 20kg. This maintenance rate is in addition to the isotonic infusion calculated for burn resuscitation and is not titrated.

3. In children with burns > 30% TBSA, early administration of may reduce overall resuscitation volume. If needed, initiate 5% albumin at the child's calculated maintenance rate (use the 4-2-1 rule) and subtract this from the isotonic fluid rate; the albumin rate is maintained while the isotonic fluid is adjusted based on UOP.

4. Monitor resuscitation in children, like adults, based on physical examination, input and output measurements, and analysis of laboratory data. The well-resuscitated child should have alert sensorium,

palpable pulses, and warm distal extremities; urine should be glucose-negative. Monitor electrolytes every 8 hours during the first 72 hours to pick up hypo- and hypernatremia and hypocalcemia. If available, monitor calcium levels and replete to maintain iCa >1.1.

5. Cellulitis is the most common infectious complication and usually presents within 5 days of injury. Prophylactic antibiotics do not diminish this risk and should not be used unless other injuries require them. Most anti-streptococcal antibiotics such as penicillin are successful in eradicating infection. Initial parenteral administration is advised for most children presenting with fever or systemic toxicity.

6. Nutrition is critical for pediatric burn patients. Nasogastric feeding may be started immediately at a low rate in hemodynamically stable patients and tolerance monitored. Start with a standard pediatric enteral formula (e.g. Pediasure) targeting 30-35 kcal/kg/day and 2g/kg/day of protein.

7. Children may rapidly develop tolerance to analgesics and sedatives; dose escalation is commonly required. Ketamine and propofol are useful procedural adjuncts.

When burned at a young age, many children will develop disabling contractures. These are often very amenable to correction which may be performed in theater with adequate staff and resources. Seek early consultation from the USAISR Burn Center (DSN 312-429-2876 (BURN); Commercial (210) 916-2876 or (210) 222-2876; email usarmy.jbsa.medcom-aisr.list.armyburncenter@health.mil).

Opportunities for pediatric surgical care provided by Non-Governmental Organizations (NGOs) may be the best option but require the coordinated efforts of the military, host nation, and NGOs.

Pediatric specific questions can be asked through the Burn consult hotline (ask to coordinate with the pediatric intensivist).

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All burn casualties (as identified by diagnosis code).

INTENT (EXPECTED OUTCOMES)

1. All burn patients with GCS < 8, symptomatic inhalation injury, deep facial burns, or burns ≥ 40% receive a definitive airway (endotracheal tube, cricothyroidotomy, or tracheostomy) prior to interfacility transfer (Role 2-Role 3 or Role 3-Role 4).
2. All patients with burns ≥ 20% TBSA receive formal fluid resuscitation documented on burn flow sheet.
3. Escharotomy is performed for circumferential full thickness burns.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest with burn ≥ 40% TBSA or GCS < 8 or inhalation injury with AIS severity code > 1 or facial burns with face AIS >2 who receive a definitive airway (endotracheal tube, cricothyroidotomy, or tracheostomy) at first surgical capability.

2. Number and percentage of patients with burn ≥ 20% TBSA who have burn flow sheet completed.

3. Number and percentage of patients with circumferential burn who receive escharotomy.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)
- Burn Navigator data

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG. It is the responsibility of the nurse assigned to the trauma patient to ensure the Burn Navigator or Burn Flow Sheet (Appendix D) is initiated and completed.

APPENDIX A: PHYSICIAN'S ORDER

1. **Diagnosis**: _____
2. **Condition**: VSI SI NSI Category: Nation/Service (e.g., US/USA, HN/IA)
3. **Allergies**: Unknown NKDA Other
4. **Monitoring**
   - 4.1. Vital signs: Q _____ hrs
   - 4.2. Urine output: Q _____ hrs
   - 4.3. Transduce bladder pressure Q _____ hrs
   - 4.4. Neurovascular/Doppler pulse checks Q _____ hrs
   - 4.5. Transduce: _____CVP _____A-line _____Ventriculostomy
   - 4.6. Neuro checks: Q _____ hrs
   - 4.7. Cardiac monitor: Yes / No
5. **Activity**
   - 5.1. _____Bedrest _____Chair Q shift _____ Ad lib _____ Roll Q 2 hrs
   - 5.2. _____Passive ROM to UE and LE Q shift
   - 5.3. Spine precautions: _____C-Collar /C-Spine _____TLS Spine
6. **Wound Care**
   - 6.1. _____NS wet to dry BID to: _____
   - 6.2. _____Dakin's wet to dry BID to: _____
   - 6.3. _____VAC dressing to _____75 mm Hg _____125 mm Hg
   - 6.4. _____Abdominal closure drains to LWS
   - 6.5. _____Other: _____
7. **Tubes/Drains**
   - 7.1. _____NGT to LCWS or _____ OGT to LCWS
   - 7.2. _____Place DHT _____Nasal _____Oral and confirm via KUB
   - 7.3. _____Foley to gravity
   - 7.4. _____Flush feeding tube Q shift with 30 mL water
   - 7.5. _____JP(s) to bulb suction; strip tubing Q 4 hrs and PRN
   - 7.6. _____Chest tube to: _____20 cm H_2O suction (circle: R L Both) or _____Water seal: (circle: R L Both)
8. **Nursing**
   - 8.1. Strict I & O and document on the JTTS Burn Resuscitation Flow Sheet Q 1 hr for burn > 20% TBSA
   - 8.2. _____Clear dressing to Art Line/CVC, change Q 7D and prn
   - 8.3. _____Bair Hugger until temperature > 36° C
   - 8.4. _____Lacrilube OU Q 6 hrs while sedated
   - 8.5. _____Oral care Q 4 hrs; with toothbrush Q 12 hrs
   - 8.6. _____Maintain HOB elevated 45°
   - 8.7. _____Fingerstick glucose Q _____ hrs
   - 8.8. _____Routine ostomy care
   - 8.9. _____Ext fix pin site care
   - 8.10. _____Trach site care Q shift
   - 8.11. _____Incentive spirometry Q 1 hrs while awake; cough & deep breath Q 1 hr while awake
9. **Diet**
   - 9.1. _____NPO
   - 9.2. _____PO diet
   - 9.3. _____TPN per Nutrition orders
   - 9.4. _____Tube Feeding: _____@ _____mL/hr OR _____Advance per protocol

10. Burn Resuscitation (%TBSA > 20%)

10.1. If available, initiate Burn Navigator computer decision support system and follow prompts on screen. System will provide recommendations for burn fluid resuscitation, provider should use clinical judgment and consider entire clinical scenario when interpreting recommendations.

10.2. Start initial infusion of Lactated Ringers (LR) at _____ml/hr IV (10 x % TBSA >40 kg <80 kg) (Add 100 ml/hr for every 10 kg > 80 Kg)

10.3. Titrate resuscitation IVF as follows to maintain target UOP (Adult: 30-50 mL/hr; Children: 1.0 mL/kg/hr)

- Decrease rate of LR by 20% if UOP is greater than 50 mL/hr for 2 consecutive hrs
- Increase rate of LR by 20% if UOP is less than 30 mL/hr (adults) or pediatric target UOP for 2 consecutive hrs

10.4. If CVP > 10 cm H_2O and patient still hypotensive (SBP < 90 mm Hg), begin vasopressin gtt at 0.02 – 0.04 Units/min

10.5. Post burn day #2 (Check all that apply)

_____Continue LR at _____ mL/hr IV

_____Begin _____@ _____mL/hr IV for insensible losses

_____Start Albumin 5% at _____ mL/hr IV ((0.3 – 0.5 x %TBSA x wt in kg) / 24) for 24 hrs

11. IVF (% TBSA ≤ 20%): ____LR ____NS ____D5NS ____D5LR ____D5 .45NS ____+ KCl 20 meq/L @ ____mL/hr

12. Laboratory Studies & Radiology

12.1. _____CBC, Chem-7, Ca/Mg/Phos: _____ ON ADMIT _____DAILY @ 0300

12.2. _____PT/INR _____TEG _____Lactate: _____ ON ADMIT _____DAILY @ 0300

12.3. _____LFTs _____Amylase _____Lipase: _____ ON ADMIT _____DAILY @ 0300

12.4. _____ABG: _____ON ADMIT _____ 30 mins after ventilator change _____Q AM (while on ventilator)

12.5. _____Triglyceride levels after 48 hours on Propofol

12.6. _____Portable AP CXR on admission

12.7. _____Portable AP CXR Q AM

13. Prophylaxis

13.1. _____Protonix 40 mg IV Q day

13.2. _____Lovenox 30 mg SQ BID OR _____Heparin 5000 U SQ TID starting_____

13.3. _____Pneumatic compression boots

14. Ventilator Settings

14.1. Mode: _____ SIMV _____CMV _____AC _____CPAP

14.2. FiO_2: _____%

14.3. Rate: _____

14.4. Tidal Volume: _____ cc

14.5. PEEP: _____

14.6. Pressure Support: _____

14.7. Insp Pressure: _____

14.8. I/E Ratio: _____

14.9. _____ APRV: Phi_____ Plow_____ Thi_____ Tlow_____ FiO_2: _____%

14.10. _____Maintain patient in soft restraints while on ventilator

14.11. _____Wean FiO_2 to keep SpO_2 > 90-96% or PaO_2 >60-100 mmHg[1]

14.12. _____nebulizer/MDIs: _____Albuterol _____Atrovent _____Xopenex Unit Dose Q 4 hrs

15. Analgesia/Sedation/PRN Medications

15.1. Analgesia/sedation goal is Richmond Agitation Sedation Scale (RASS), scale below, of 0 (alert and calm) to -3 (moderate sedation). Hold continuous infusion for RASS of -4 (deep sedation) or higher.

15.2. _____Propofol gtt at _____ mcg/kg/min, titrate up to 50 mcg/kg/min.

15.3. _____Fentanyl gtt at _____mcg/hr titrate up to 250 mcg/hr; for analgesia may give 25-100 mcg IVP Q 15 minutes for acute pain or burn wound care.

15.4. _____Morphine gtt at _____mg/hr, titrate up to 10 mg/hr, for analgesia may give 2-10 mg IVP Q 15 minutes for pain or burn wound care.

15.5. _____Versed gtt at _____ mg/hr, titrate up to 10 mg/hr ; may give 2-5 mg IVP Q 15 minutes for acute agitation or burn wound care.

15.6. _____Ativan gtt at _____mg/hr, titrate up to 10 mg/hr; may give 1-4 mg IVP Q 2-4 hours for acute agitation.

15.7. Important: Hold continuous IV analgesia/sedation at 0600 hrs for a RASS of -4 or -5. If further analgesia/sedation is indicated, start medications at ½ of previous dose and titrate for target RASS.

15.8. _____Morphine 1-5 mg IV Q 15 minutes prn pain

15.9. _____Fentanyl 25-100 mcg IV Q 15 minutes prn pain

15.10. _____Ativan 1-5 mg IV Q 2-4 hrs prn agitation

15.11. _____Percocet 1-2 tablets po Q 4 hrs prn pain

15.12. _____Tylenol _____ mg / Gm PO / NGT / PR Q _____ hrs PRN for fever or pain

15.13. _____Morphine PCA; Program (circle one): 1 2 3 4

15.14. _____Zofran 4-8 mg IVP Q 4 hrs PRN for nausea/vomiting

15.15. _____Dulcolax 5 mg PO / PR Q day PRN for constipation

16. Specific Burn Wound Care

16.1. Cleanse and debride facial burn wounds with Sterile Water or (0.9% NaCl) Normal Saline Q 12 hrs, use a washcloth or 4x4s to remove drainage/eschar

16.2. Cleanse and debride trunk and extremities with chlorhexidine gluconate 4% solution (Hibiclens) and Sterile Water or Normal Saline, before prescribed dressing changes

16.3. Change fasciotomy dressings and outer gauze dressings daily and as needed; moisten with sterile water Q 6 hours and as needed to keep damp, not soaking wet.

Face & Ears

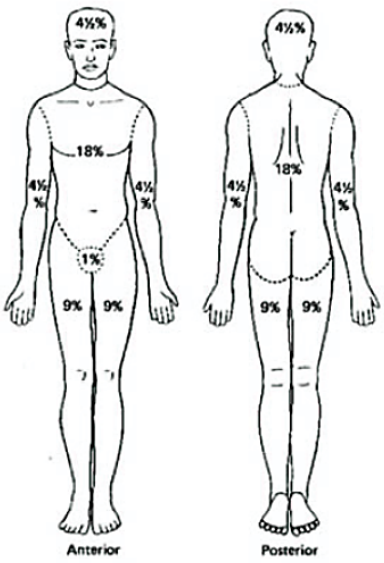
_____Bacitracin ointment BID &PRN
_____Sulfamylon cream to ears BID & PRN
_____5% Sulfamylon solution dressing changes Q AM and moisten every 6 hrs
_____Bacitracin ophth ointment: apply OU Q 6 hrs

BUEs & Hands, BLEs, Chest, Abdomen & Perineum

_____Silvadine cream Q AM & PRN (*deep partial & full thickness*)
_____Sulfamylon cream Q PM & PRN (*deep partial & full thickness*)
_____5% Sulfamylon solution – change Q AM & moisten Q 6 hrs (*superficial burns)*
_____Silver nylon dressing and moisten with sterile water approximately every 6 hrs PRN; dressings may be left in place for 72 hrs)

Back

_____Silvadine cream Q AM & PRN (*deep partial & full thickness burns*)
_____Sulfamylon cream Q PM & PRN (*deep partial & full thickness burns*)
_____5% Sulfamylon solution dressings changed Q AM and moisten Q 6 hrs
_____ Silver nylon dressing and moisten with sterile water approximately every 6 hrs PRN; dressings may be left in place for 72 hrs)



Rule of Nines to calculate initial burn size

17. Other Orders

17.1. _____

17.2. _____

18. Notify Physician if: SBP < _____, MAP < _____, HR <_____ or > _____, SaO_2 < _____%, T > _____, UOP < 30 mL/hour for 2 consecutive hours

1.Ginde AA. Strategy to Avoid Excessive Oxygen (SAVE-O2) in Critically Ill Trauma Patients: A Multicenter Cluster-Randomized, Stepped Wedge Trial for Targeted Normoxemia. Scientific Plenary Presentation (MHSRS-23-10446), Military Health System Research Symposium; August 14, 2023. Ginde AA. Strategy to Avoid Excessive Oxygen (SAVE-O2) in Critically Ill Trauma Patients: A Multicenter Cluster-Randomized, Stepped Wedge Trial for Targeted Normoxemia. Scientific Plenary Presentation (MHSRS-23-10446), Military Health System Research Symposium; August 14, 2023.

RICHMOND AGITATION SEDATION SCALE (RASS)

Score	Term	Description
+4	Combative	Overtly combative or violent; immediate danger to staff
+3	Very agitated	Pulls on or removes tube(s) or catheter(s) or has aggressive behavior toward staff
+2	Agitated	Frequent nonpurposeful movement or patient–ventilator
+1	Restless	Anxious or apprehensive but movements not aggressive or vigorous
0	Alert and calm	Spontaneously pays attention to caregiver
-1	Drowsy	Not fully alert, but has sustained (more than 10 seconds) awakening, with eye contact, to voice
-2	Light sedation	Briefly (less than 10 seconds) awakens with eye contact to voice
-3	Moderate sedation	Any movement (but no eye contact) to voice
-4	Deep sedation	No response to voice, but any movement to physical stimulation
-5	Unarousable	No response to voice or physical stimulation

APPENDIX D: JTS BURN RESUSCITATION PROTOCOL, WORKSHEET & FLOW SHEET

THE BURN RESUSCITATION PROTOCOL

The JTS Burn Resuscitation Flow Sheet provides clinicians with a tool to track burn resuscitation over a 72-hour period. Conceptually, the flow sheet creates a continuum between clinicians during the resuscitation phase. This format allows clinicians to accurately trend intake and output, hemodynamics and vasoactive medications, and promotes optimal outcomes through precise patient management.

1. The clinicians at the first medical facility where the patient receives treatment will initiate the JTTS Burn Resuscitation Flow Sheet. This treatment facility will be listed in the "Initial Treatment Facility" block. Clinicians at any level of care may initiate the flow sheet.
2. Record today's date in the "Date" block according to the current date where the recorder is located. (Do not adjust this date based on the patient's origin or destination; use the local date).
3. Record the patient's full name and social security number in the "Name" and "SSN" blocks. Document name and SSN on all three pages of the flow sheet.
4. Record the patient's weight in the "Pre-burn est. wt (kg)" block. In theater, record the estimated weight based on the patient's weight prior to injury or "dry weight." If a patient presents prior to initiating resuscitation and an accurate weight can be easily obtained without delaying care, providers are urged to weigh the patient and record the result.
5. Record the total body surface area burned in the "%TBSA" block (do not include superficial injury in this calculation). Clinicians will assess the burn size and use this value to determine fluid resuscitation requirements. Following the patient's transfer to another facility, the receiving clinicians are required to "re-map" the burn, considering that burn wound may "convert" (or become deeper) between assessments at one facility or during transport between two facilities.
6. Burn Fluid Resuscitation Calculations: Use the Rule of Tens to determine fluid requirements for the first 24 hours post-burn. (Rule of Tens: 10 x % TBSA > 40 kg and < 80 kg; if > 80 kg, add 100 ml/hr for every 10 kg > 80 kg). At 8-12 hours post-burn, reevaluate resuscitation efforts and assess for potential over resuscitation. If fluid resuscitation needs exceed 6 ml/kg/%TBSA in 24 hours, consider the guidelines established in the *Emergency War Surgery Handbook* and the addendum to the handbook, "Recommendations for Level IV Burn Care." *[LRMC specific: USAISR/BAMC Burn Unit Guidelines can also be found in the LRMC Burn Care Guide.]*
    a) Clinicians at the first medical facility to treat the patient will calculate the fluid requirements for the first 24 hours post-burn and record the amount in the block on page 1 labeled "Estimated fluid volume patients is administered,"
    b) Clinicians will record the "fluid volume ACTUALLY received" during the first 24 hours of resuscitation in the block labeled as such at the top of page 2. This amount will equal the actual volume delivered during the first 24 hours (as recorded on page 1).
    c) Clinicians will transcribe the 24-hour fluid volume totals recorded on pages 1 and 2 of the flow sheet onto page 3 in the block labeled "fluid volume ACTUALLY received." This allows clinicians to see the first 48-hour totals as the patient enters into the last 24 hours of the 72-hour period.
7. Record the local date and time that the patient was injured in the "Date & Time of Injury" block. This date and time IS NOT the time that the patient arrived at the medical facility, but rather the date and time of INJURY.

8. Record the facility name and/or treatment team in the "Tx Site/Team" block. The facility name/team name is the team of clinicians who managed the patient during each specified hour on the flow sheet. This team may reside within a facility, in which case the facility name is recorded, or be a transport team (e.g., MEDEVAC, CCATT, AEROVAC).
9. "Hr from burn" is defined as the number of hours after the burn injury occurred. If a patient does not arrive at a medical facility until 3 hours after the burn occurred, clinicians do not record hourly values for hours 1-3 but begin recording the row marked "4th" hour post-burn. To the extent possible, clinicians should confer with level I and II clinicians to determine fluid intake and urine output. These totals may be record in the 3rd hour row.
10. Record the current local time of the recorder in the "Local Time" block, be it Baghdad Time, Berlin Time, ZULU, or CST. As with date do not adjust time based on the patient's origin or destination; use the local time.
11. Record the total volume of crystalloids and colloids administered in the "crystalloid/colloid" column, not the specific fluids delivered. Clinicians should refer to the critical care flow sheet to determine the fluids types and volumes. This burn flow sheet is designed to track total volumes. Examples of crystalloid solutions are LR, 0.45% NS, 0.9% NS, D5W, and D5LR. Examples of colloids are Albumin (5% or 25%), blood products, and other volume expanders such as dextran, hespan, or hextend. The use of hydroxyl ethyl starch (hextend) as a resuscitation fluid is no longer recommended.
12. Document the name, dosage, and rate of vasoactive agents in the "Pressors" block. Patients who receive vasoactive agents may also have invasive pressure monitoring devices (e.g., arterial line, central venous line, pulmonary artery catheter), in which case significant values should be recorded in the "BP" and MAP (>55)/CVP" columns.
13. For additional burn resuscitation guidelines refer to the *Emergency War Surgery Handbook* and the *Recommendations for Level IV Burn Care*.

JTS BURN RESUSCITATION WORK SHEET

Initiate AFTER *completion of trauma assessment and interventions*
Adults only: *Refer to Additional Considerations for Pediatric Burn Patients in the Burn Care CPG.*

1. Contact USAISR Burn Center (DSN 312-429-2876) or email: usarmy.jbsa.medcom-aisr.list.armyburncenter@health.mil

Date/Time contact: _____POC:_____ by:_____

2. Estimated Pre-burn Weight (wt): _____kg (Average Service Members are 82 ± 15 kg)

3. Estimate Total Burn Surface Area (TBSA) using Rule of Nines (refine with Lund-Browder after wounds are cleansed)

Partial thickness (2nd)_____% + Full thickness (3rd)_____% = **TBSA_____%**

IF TBSA >40%: intubate (use ETT ≥ 7.5 fr to facilitate bronchoscopy)

IF TBSA <15%: formal resuscitation may not be required, provide maintenance and/or oral fluids

4. Standard Burn Resuscitation Fluid: Lactated Ringers (LR) or Plasmalyte

5. Calculate INITIAL Fluid Rate using Rule of 10 (adults):

- IF wt < 40kg: 2ml x %TBSA_____ x wt(kg)_____ ÷ 16 = _____ml/hr
- IF wt ≥ 40kg: %TBSA_____ x 10 = _____ml/hr
  - IF wt > 80kg: add 100ml/hr to initial rate for every 10 kg>80: adjusted initial fluid rate = _____ml/hr
  - (Example: 100kg patient with 50% TBSA burn = 50% x 10 = 500 ml + 200 ml = 700 ml for first hour)

6. If Inhalation Injury Present: administer aerosolized heparin in albuterol (5,000 units Q4 hours)

7. Titrate Resuscitation Fluid: maintain target **UOP 30-50ml/hr** (Q 1 hour)

- If rhabdomyolysis present: use target UOP 75-100 ml/hr (Contact USAISR Burn Center DSN 312-429-2876)
- Goals: UOP >30 but <50ml/hr; adequate tissue perfusion (normalized lactate/base deficit), MAP >55 mmHg
- Minimum fluid rate 125mL/hr LR
- * Avoid fluid boluses
- ** Too much fluid as dangerous as too little

High risk for over resuscitation/abdominal compartment syndrome:

- If hourly rate >1500mL/hr x 2 hrs OR
- If total 24 hr volume exceeds: wt(kg) x 250ml= _____ml (includes all infused fluids)
  - Contact USAISR Burn Center (DSN 312-429-2876)
  - Consider adjuncts (below)
  - Check bladder pressures Q4hrs (>20 mmHg notify physician)
  - Avoid surgical decompression (significant mortality risk in burns)

Adjuncts:

1. Colloids: 5% albumin/FFP (Use hextend only if others unavailable; Hextend, as a resuscitation fluid, is no longer recommended.)
   - * Colloids not preferred until hour 8-12; can consider earlier in difficult resuscitation
   - Infuse at ml/hr according to chart below based on adult patient weight and burn size
2. Vasopressors: Contact USAISR Burn Center (DSN 312-429-2876)

5% Albumin Infusion (ml/hr)	30-49%TBSA	50-69% TBSA	70-100% TBSA
<70 kg	30	70	110
70-90 kg	40	80	140
>90 kg	50	90	160

Ensure adequate volume (CVP trend 6-8 cm H_2O); **maintain MAP > 55 mmHg**

- Maintain ionized Ca >1.1 mmol/L
- Start with vasopressin 0.04 units/min. **DO NOT TITRATE**
- Second line pressor: norepinepherine 2-20mcg/min
- Refractory shock: consider epinephrine or phenylephrine infusion
- Refractory shock: consider adrenal insufficiency, give hydrocortisone 100mg IV Q8 hrs
- Manage acidemia (pH<7.2): use ventilator interventions first, then bicarbonate or THAM infusion
- Renal replacement therapy if available (Contact USAISR Burn Center DSN 312-429-2876)

Assessment/Interventions:

- Complete full secondary trauma exam
- Ensure thermoregulation; administer warmed fluids; cover with space blanket; elevate burned extremities
- Superficial burn (1st degree): Sunburn, no blister, blanch readily; NOT included in TBSA
- Partial thickness (2nd degree): Blanch, moist, blisters, sensate
- Full thickness (3rd degree): Leathery, white, non-blanching, dry, insensate, thrombosed vessels
- Protect eyes with moisture shields if corneas exposed or blink reflex slow; apply ophthalmic erythromycin ointment at least Q2hrs.
- **Prompt intubation for facial burns, suspected inhalation injury, TBSA >40%**
    - Anticipate induction-associated hypotension.
    - Secure ETT with cloth tie, not adhesive tape
    - Reassess ETT position at teeth Q1 hour as edema develops and resolves
    - Intubated patients require oro/naso-gastric tube for decompression.
    - Administer IV proton-pump inhibitor.
- Monitor bladder pressure at least Q4hrs for large burns or high volume resuscitations
    - Abdominal compartment syndrome: decreased UOP, increased pulmonary pressures, difficulty ventilating, bladder pressure remains > 20 mmHg
    - Avoid decompressive laparotomy; consider percutaneous peritoneal drainage
    - Reduce crystalloid volume using colloid or vasopressors
- Monitor pulses hourly: palmar arch, dorsalis pedis, posterior tibial with Doppler
    - Consider escharotomy if signal diminished; refer to Burn CPG for technique (Call USAISR Burn Center DSN 312-429-2876)
- Monitor extremity compartment pressures as clinically indicated
    - Elevate burned extremities at all times
    - Extremity compartment syndrome: pain, paresthesia, pallor, paralysis, pulselessness (late sign)
    - Fasciotomy may be required
- Wound care
    - Thoroughly cleanse burn wounds, preferably in Operating Room
    - Select topical antimicrobial in consultation with Burn Surgeon (Call USAISR Burn Center DSN 312-429-2876) based on product availability, expected transport time, etc.
    - Acceptable to cover burns with dry sheets or clean dressings for first 48 hours
- All definitive burn surgery done at USAISR Burn Center for US Service Members (DSN 312-429-2876)

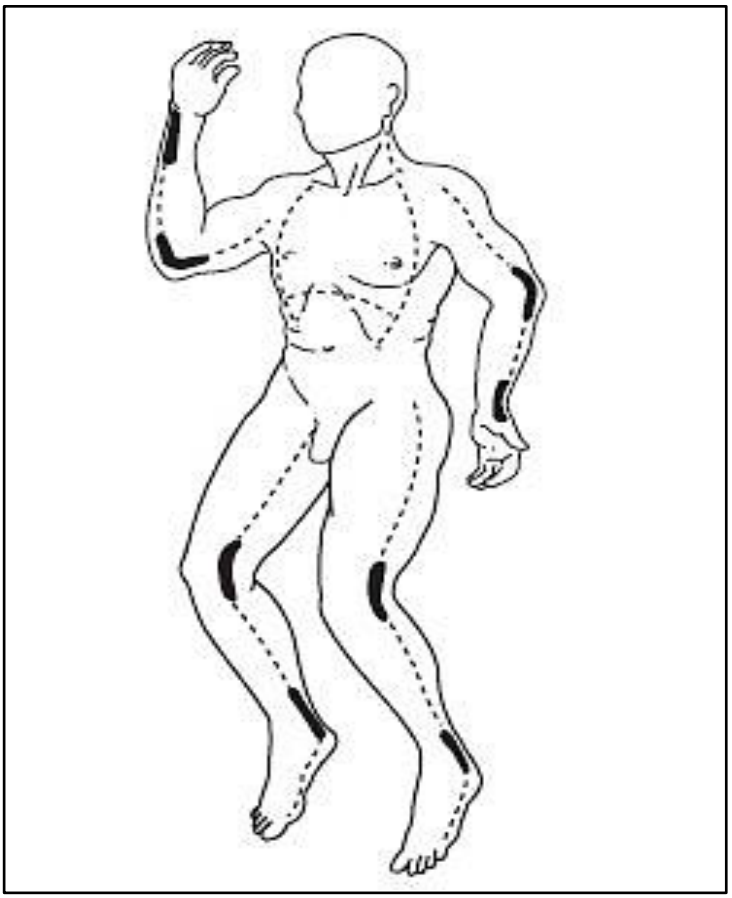
APPENDIX E: ESCHAROTOMY FIGURE



Dashed lines indicate the preferred sites for escharotomy incisions. **Bold lines** indicate the importance of extending the incision over involved major joints. Incisions are made through the burned skin into the underlying subcutaneous fat using a scalpel or electrocautery. For a thoracic escharotomy, begin incision in the midclavicular lines. Continue the incision along the anterior axillary lines down to the level of the costal margin. Extend the incision across the epigastrium as needed. For an extremity escharotomy, make the incision through the eschar along the midmedial or midlateral join line.

Figure 26.2-1 Emergency War Surgery; Fourth United States Revision; 2013 (page 379).

APPENDIX F: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Burn Wound Management in Prolonged Field Care (CPG ID: 57)

This Role 1 prolonged field care (PFC) guideline is intended to be used after Tactical Combat Casualty Care (TCCC) Guidelines, when evacuation to higher level of care is not immediately possible.

INTRODUCTION

This Role 1, prolonged field care (PFC) guideline is intended to be used after Tactical Combat Casualty Care (TCCC) Guidelines, when evacuation to higher level of care is not immediately possible. A provider of PFC must first and foremost be an expert in TCCC. This Clinical Practice Guideline (CPG) is meant to provide medical professionals who encounter burns in austere environments with evidence-based guidance. Recommendations follow a "best," "better," "minimum" format that provides alternate or improvised methods when optimal hospital options are unavailable. A more comprehensive guideline for burn care is available in the Joint Trauma System Clinical Practice Guideline (JTS CPG) for Burn Care at https://jts.health.mil/index.cfm/PI_CPGs/cpgs

URGENT BURN CARE

Burns covering >20% of the total body surface area (TBSA), or those with smoke inhalation injury (and airway or breathing problems), are life threatening. Burns that affect vision, decrease hand function, or cause severe pain can take the warfighter out of action.

Hypothermia risk is high in burn patients. Anticipate that all burn casualties will become hypothermic and take immediate measures to prevent it by covering patient. Aggressively rewarm if temperature falls below 36°C (96.8°F).

Telemedicine: Management of burns is complex. Also, burns are highly visual and a lot can be communicated via pictures or video. Establish telemedicine consult as soon as possible.

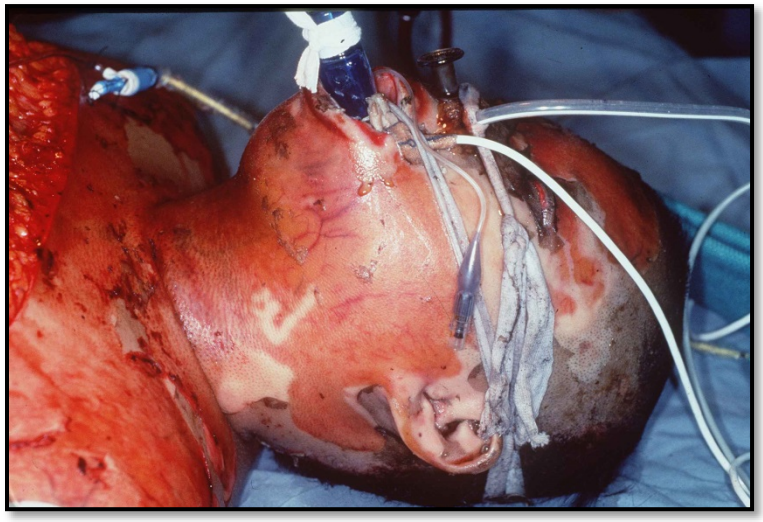
AIRWAY MANAGEMENT

Goal: Avoid airway obstruction due to inhalation injury or burn-induced swelling.

- Patients with smoke inhalation injury may present with a range of symptoms in terms of severity.
- Patients with severely symptomatic smoke inhalation injury (e.g., respiratory distress, stridor) require immediate definitive airway (cuffed tube in trachea) because they are at risk of immediate airway loss. Oxygenate and ventilate.
- All patients with burns covering >40% TBSA should be intubated because total-body swelling will tend to obstruct the airway. Patients with facial burns around the mouth may require intubation (Figure 1).

Figure 1. Severe facial burns with airway secured.



- **Best:** Rapid-sequence intubation by skilled provider, followed by continuous sedation and airway maintenance, supplemental oxygen, portable ventilator.
- **Better:** Cricothyroidotomy followed by continuous sedation and airway maintenance, supplemental oxygen via an oxygen concentrator, portable ventilator.
- **Minimum:** Cricothyroidotomy, ketamine, ambu bag with positive end-expiratory pressure (PEEP) valve.

NOTES:

- Patients with mild symptoms of smoke inhalation injury (e.g., some cough, no respiratory distress) can be observed.
- Burns or explosions in a closed space are associated with higher risk of inhalation injury than burns occurring in open areas.
- Supraglottic airway (e.g., laryngeal mask airway [LMA], King LT [Ambu, http://www.ambuusa.com/], or Combitube [Medtronic Minimally Invasive Therapies, http://www.medtronic.com/covidien]) is not appropriate because edema will continue to increase over 48 hours and these tubes do not overcome vocal-cord edema.
- Endotracheal tube must be secured circumferentially around the neck using cotton ties or similar. Tape does not stick to the face well enough in burn patients.
- Place nasogastric (or orogastric) tube to decompress stomach in intubated patients.
- Perform frequent endotracheal suction of intubated patients to ensure tube patency and remove mucus/debris (approximately once an hour or more frequently if oxygen saturation [SpO2] drops).
- If there is evidence of inhalation injury, use 3–5mL of endotracheal saline to facilitate suctioning and prevent tube insipation and obstruction.
- Monitoring end-tidal CO2 is an important capability for all intubated patients. A rising end-tidal CO2 could indicate clogging of endotracheal tube or poor ventilation from another cause (e.g., bronchospasm, tight eschar across chest).

- Use PEEP on all intubated patients.
- Perform a surgical escharotomy of the chest for tight, circumferential, full-thickness burns that impair breathing. Incision goes through the full thickness of the burn and into the fat (Appendix A). Expect some pain and bleeding.
- Use bronchodilators (e.g., albuterol inhaler) for intubated patients with inhalation injury, if available.

Ventilator management of burn patients can be complicated and evolve as pulmonary conditions change due to volume overload/edema and acute respiratory distress syndrome (ARDS). Telemedicine consultation with skilled providers is recommended.

ASSESS BURN SIZE

Goal: Accurately identify burn wound size to identify appropriate fluid resuscitation needs.

Estimating burn wound size may be difficult. Engage remote specialty consultants early. If possible, send pictures of wounds that have been cleaned and debrided.

- **Best:** When wounds are cleaned/debrided, recalculate TBSA using the Lund-Browder chart (Appendix B).
- **Better:** Same as minimum.
- **Minimum:** For small wounds, calculate the size of the wound by using the patient's hand size (including fingers) to represent a 1% TBSA. For larger wounds, calculate the patient's initial burn size using the Rule of Nines (Appendix C).

NOTE: Significant over- or underestimation of burn wound size (by more than 10%) may lead to significant morbidity. Underestimation may lead to under-resuscitation and organ failure (i.e., renal failure, shock); overestimation may lead to resuscitation morbidity (i.e., respiratory failure, compartment syndromes).

1st degree (superficial) burns look like a mild-moderate sunburn. They appear red, blanch readily, do not blister, and hurt when touched. Do NOT include these wounds in the estimation of TBSA used for fluid resuscitation (Figure 2).

2nd degree (partial thickness) burns are moist, blister, blanch, and hurt. Include these wounds in the TBSA estimation (Figure 3).

3rd degree (full thickness) burns appear leathery, dry, nonblanching, do not hurt, and often contain thrombosed vessels that are visible. Include these wounds in the TBSA estimation (Figure 4).

Figure 2. First degree burns. (Do not include these wounds in the TBSA estimate!)

B. Mostly first degree burns with small area of superficial second degree.

Figure 3. Second-degree burns

A. Second-degree burn with intact blisters.

B. Deep (D), intermediate (I) & superficial (S) second degree burns.

Figure 4. Third-degree burns

A. Third-degree burn before cleaning and debridement of loose, dead skin.

B. Third-degree burn with eschar.

Figure 4. Third-degree burns (Continued)

C. Third-degree burns after cleaning and debridement and escharotomy.

D. Extensive third-degree burns with eschar formation.

FLUID RESUSCITATION

Goal: Over the first 24–48 hours post burn, plasma is lost into the burned and unburned tissues, causing hypovolemic shock (when burn size is >20%). The goal of burn-shock resuscitation is to replace these ongoing losses while avoiding over-resuscitation.

Best: Isotonic crystalloids (e.g., lactated Ringer's, Plasma-Lyte IV [Baxter, http://www.baxter.com/]);

- Start intravenous (IV) or intraosseous (IO) administration IMMEDIATELY.
- IV/IO can be placed through burned skin if necessary.
- NO bolus (unless hypotensive, in which case, bolus only until palpable pulses are restored).
- Initial IV rate 500mL/h; start while completing initial assessment.
- Adults: Measure burn size (TBSA) and multiply by 10. This is now your IV fluid rate. For example, if the burn size is 30%: 30 × 10 = 300. Starting rate is 300mL/h.
  - For patients with weight >80kg, add an extra 100mL/h for each 10kg. For example, for a 100kg patient with 30% burns, the starting rate is 300mL/h + 200mL/h = 500mL/h.
  - If resuscitation is delayed, DO NOT try to "catch up" by giving extra fluids.
  - For children, 3 × TBSA × body weight in kg gives the volume for the first 24 hours. One half is given during the first 8 hours.

Better: Enteral (oral or gastric) intake of electrolyte solution

- Sufficient volume replacement will require "coached" drinking on a schedule using approximately the same amount of fluids that would be given IV/IO (see above).
- Oral resuscitation of patients with burns up to about 30% TBSA is possible (see Hydration side bar below).
- If a nasogastric tube (NGT) is available, it is preferable to resuscitate with infusion of electrolyte solution via NGT (e.g., 300–500mL/h. But watch for nausea/vomiting.

Minimum: Rectal infusion of electrolyte solution**.** Rectal infusion of up to 500mL/h can be supplemented with oral hydration (see Hydration side bar.)

Hydration

Plain water is ineffective for shock resuscitation and can cause hyponatremia. If using oral or rectal fluids, they must be in the form of a premixed or improvised electrolyte solution to reduce this risk.

Examples:

- World Health Organization (WHO) Oral Rehydration Solution (per package instructions or 1L of potable water with 6 level teaspoons sugar, 0.5 level teaspoon salt)
- Mix 1L of D5W solution with 2L of Plasma-Lyte
- Per 1L water: add 8tsp sugar, 0.5tsp salt, 0.5tsp baking soda
- Per quart of Gatorade (Stokely-Van Camp Inc., http://www.gatorade.com/): add 0.25tsp salt, 0.25tsp baking soda (If no baking double the amount of salt in the recipe.)

The principles of hypotensive resuscitation according to TCCC DO NOT apply in the setting of burns (without severe bleeding).

HOWEVER

In the unusual setting of burns associated with noncompressible (e.g., thoracic, abdominal, pelvic) hemorrhage, aggressive fluid resuscitation may result in increased hemorrhage. Balancing the risk of uncontrolled hemorrhage against the risk of worsening burn shock from under-resuscitation should be guided by expert medical advice (in-person or telemedicine). Be prepared for blood transfusion.

MONITORING

Goal: Maintain adequate oxygenation and ventilation, avoid hypotension, trend response to resuscitation. Document blood pressure (BP), heart rate (HR), urine output (UO), mental status, pain, pulse oximetry, and temperature, and record data on a flow sheet (Appendix D).

VITAL SIGNS

- **Best:** Portable monitor providing continuous vital-signs display; capnography if intubated; document vital-signs trends frequently (every 15 minutes initially, then every 30–60 minutes once stable for more than 2 hours).
- **Better:** Capnometry in addition to minimum requirements (if intubated).
- **Minimum:** blood-pressure cuff, stethoscope, pulse oximetry, document vital-signs trends frequently.

URINE OUTPUT

Urine output (UO) is the main indicator of resuscitation adequacy in burn shock.

Goal: Adjust IV (or oral/rectal intake) rate to UO goal of 30–50mL/h. For children, titrate infusion rate for a goal UO 0.5–1 mL/kg/hr.

- **Best:** Place Foley catheter
  - If UO too low, increase IV rate by 25% every 1–2 hours (e.g., if UO = 20mL/h and IV rate =300mL/h, increase IV rate by 0.25 × 300 =75mL/h. New rate is 375mL/h.)
  - If UO too high, decrease IV rate by 25%.
- **Better:** Capture urine in premade or improvised graduated cylinder
  - Collect all spontaneously voided urine and carefully measure; >180mL every 6 hours is adequate for adults.
  - A Nalgene® (Thermo Fisher Scientific Inc., http://www.nalgene.com/) water bottle is an example of an improvised graduated cylinder)
- **Minimum:** Use other measures
  - If unable to measure UO, adjust IV rate to maintain HR less than 140, palpable peripheral pulses, good capillary refill, intact mental status.
  - Measure the BP and consider treating hypotension, but remember: BP does not decrease until relatively late in burn shock, because of catecholamine release. On the other hand, BP may be inaccurate (artificially low) in burned extremities.

NOTE: Electric injury

- Patients with high-voltage electric injury causing muscle damage and gross pigment in the urine (and similar patients, such as rhabdomyolysis or crush injury) have a higher target UO of 70–100mL/h in adults. See PFC Crush CPG.
- If this does not cause gradual clearing of the pigment (urine turns lighter on three or four hourly checks), the patient likely needs urgent surgery for decompression/debridement

EXTREMITY BURNS

Burned extremities are vulnerable to injury from post burn swelling.

Goal: Prevent and manage swelling (edema) of burned extremities to prevent long-term damage.

- **Best:** Elevate burned extremities above heart level. Encourage patient to exercise burned extremities to decrease edema. Monitor peripheral pulses on all burned extremities hourly, using a Doppler flowmeter if available. If the peripheral pulses are diminished or absent and evacuation will be delayed, perform escharotomies of circumferential burns to restore blood flow (Appendix A). Be prepared to stop bleeding with combat gauze, electrocautery, or tourniquet as needed. Anticipate blood loss and prepare for blood transfusion.

Obtain teleconsultation.

- **Better:** Consider doing escharotomies for circumferential full thickness (3rd degree) burns of an extremity if extremity is edematous, you are unable to palpate distal pulses, and evacuation will be delayed. Anticipate blood loss and prepare for blood transfusion.

Obtain teleconsultation.

- **Minimum:** Triage patient to more rapid evacuation if extremity is edematous and you are unable to palpate distal pulses. Elevate burned extremities above heart level and have patient exercise or provide passive range of motion (PROM) to burned extremities to mobilize edema. Provide pain control to enable PROM.

PAIN MANAGEMENT

Refer to Analgesia and Sedation Management CPG for Prolonged Field Care.

Burns can be painful and can cause hypovolemia. Thus, frequent, smaller doses of an IV opioid or ketamine are preferred.

- In hypovolemic burn patients, ketamine can be used for severe pain or for painful procedures, but less than the full anesthetic dose is safer (e.g., 0.1–0.2mg/kg IV push, assess response and redose ketamine as needed every 5–10 minutes).
- For prolonged care of burn patients, a ketamine infusion may provide more consistent analgesia and help conserve supplies of analgesic medications.
- Burn wound care is extremely painful. Ensure an adequate supply of analgesic agents is available before starting wound cleaning, debridement, escharotomy, or dressing change. Refer to Analgesia and Sedation CPG or obtain telemedicine advice for adequate dosing of procedural analgesia for burn care.
- Consider administering an oral or IV benzodiazepine for anxiety (common with repeated painful wound care).

INFECTION

Burn wounds are easily infected.

Goal: Prevent burn wound infection through wound care. If evacuation to higher level of care is anticipated within 24 hours, simply cover burns with clean, dry gauze and leave intact blisters in place. Always avoid wet dressings, because of the risk of hypothermia. If evacuation is not anticipated for more than 24 hours, and time, medication, and human resources permit, provide wound care as soon as possible after the injury (within the first 24 hours). If resources are not available initially, provide wound care as soon as possible.

- **Best**: Clean wounds and debride loose dead skin by scrubbing gently with gauze and chlorhexidine gluconate solution (e.g., Hibiclens, Mölnylcke Health Care, http://www.hibiclens.com/) in clean water; apply topical antimicrobial cream (silver sulfadiazine [Silvadene, Pfizer Inc., http://www.pfizer.com/] or mafenide acetate [Sulfamylon, Mylan, http://www.mylan.com/]), followed by gauze dressing. Repeat daily.

  Alternative: instead of cream, use silver nylon dressing (Silverlon, Argentum Medical, http://www.silverlon.com/), covered by gauze dressing.

  - Silverlon can be left in place for 3–5 days as long as the wound is clean when the Silverlon is applied.

- The outer gauze dressings (e.g., Kerlix [Covidien]) should be moistened (not soaked) at least daily. Use sterile (or at least clean, uncontaminated) water or normal saline.
- The outer gauze dressings should be changed, leaving the Silverlon in place, sooner than 3 days if they become saturated with exudate or otherwise dirty.
- If the patient develops any evidence of infection, the Silverlon must be removed and the wound inspected sooner than 3–5 days.
- The Silverlon can be removed and cleaned in sterile, or at least clean uncontaminated, water and reused for up to 5 days.

- **Better:** Clean wounds and debride loose dead skin by washing with any antibacterial soap in clean water, dress wounds with any available dressings; optimize wound and patient hygiene to the extent possible given environment.
- **Minimum:** Cover with clean sheet or dry gauze. Leave blisters intact. Avoid wet dressings.

ANTIBIOTICS

- IV or oral antibiotics are not normally used for prophylaxis in burn patients in the absence of other open wounds requiring them (e.g., open fractures.)
- After several days, if patient develops cellulitis (spreading erythema around edges of burn), treat for gram-positive organisms, (e.g., cefazolin or clindamycin).
- If patient develops invasive burn wound infection (signs: sepsis/septic shock, changes in color of wound, possible foul smell of wound), treat with broad-spectrum antibiotics to include gram-positive and gram-negative coverage that ideally includes coverage for Pseudomonas aeruginosa (e.g., ertapenem + ciprofloxacin).

Fluid and equipment planning considerations. See Appendix E.

Summary Table. See Appendix F.

ABOUT THE AUTHORS

COL (Ret) Cancio, MC, USA, is the senior burn surgeon at the US Army Burn Center. He directs the Multi-Organ Support Task area. He deployed as 504 Parachute Infantry Regiment Surgeon, 82d Airborne Division, Operation Just Cause and Desert Storm; with SOCCENT and 86th Combat Support Hospital during Operation Iraqi Freedom; and with a Forward Surgical Team during Operation Enduring Freedom.

MAJ Powell, MC, USA, is an intensive care physician currently serving as the 4th Battalion 3rd Special Forces Group (Airborne) Surgeon and a staff intensivist at Womack Army Medical Center.

MSgt Adams, USAF, is an IDMT-P, FP-C, ATP, and Combat Aviation Advisor with the Air Force Special Operations Air Warfare Center (AFSOAWC)/Irregular Warfare Directorate, where he directs/coordinates Aviation Foreign Internal Defense/Global Health Engagement missions in Special Operations Command Africa (SOCAF). He has served multiple deployments to Iraq/Afghanistan and Africa supporting Base Support Operations, casualty evacuations (CASEVAC) and the CAA TCCC/CASEVAC missions. He also works part-time as a civilian critical care flight paramedic.

LT Bull, MC, USN, formerly the Battalion Surgeon for 3d Marine Raider Battalion, Marine Special Operations Command, is a family medicine resident at Naval Hospital Camp Lejeune. He is also a Navy Undersea Medical Officer.

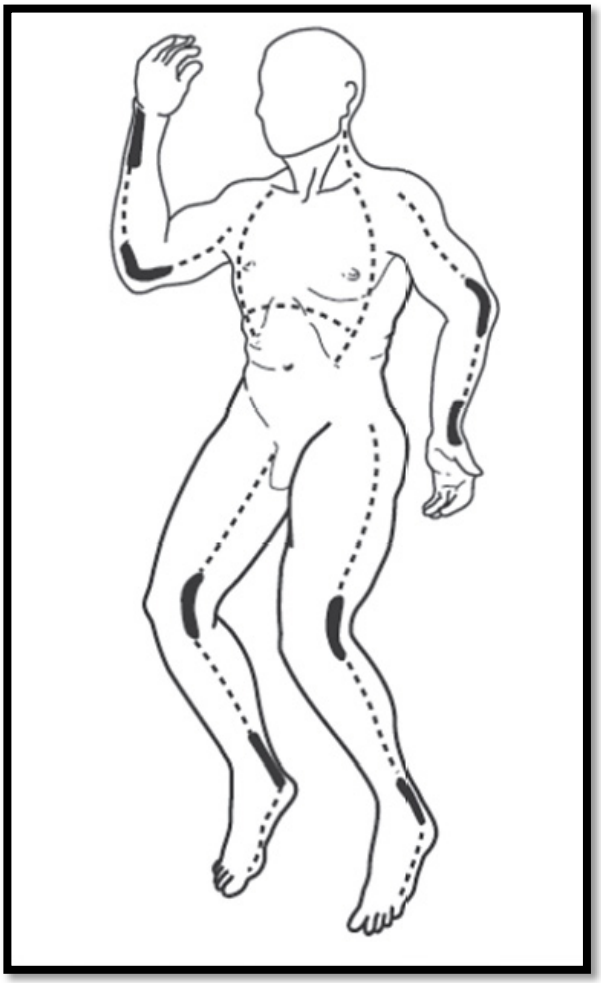
Maj Keller, MC, USAF, is an emergency medicine physician serving as the group surgeon for the 720th Special Tactics Group (AFSOC). He previously served as a CSAR flight surgeon with multiple deployments to Iraq and Afghanistan supporting rescue forces. Maj Keller is also an experienced tactical EMS provider having provided support to multiple law enforcement agencies to include the Dayton Police Department SWAT and Vice Squad, as well as the FBI.

LTC Gurney, MC USA, is a general, trauma, and burn surgeon and currently works as the Chief of Trauma Systems Development, Joint Trauma System, and the Deputy Director of the Burn Center in San Antonio, Texas. She has multiple deployments to Iraq and Afghanistan as part of Combat Support Hospitals and Forward Surgical Teams.

LTC Pamplin, MC, USA, is a board-certified intensivist and is currently the Director of Virtual Critical Care at Madigan Army Medical Center, Joint Base Lewis-McChord, Washington. Previously, he was the Director of the US Army Burn Intensive Care Unit and Chief of Clinical Trials in Burns and Trauma at the US Army Institute of Surgical Research, San Antonio, Texas, and has served as the Simulation and Training Director for the Extracorporeal Membrane Oxygenation Program, San Antonio Military Medical Center, and the Director of the Surgical Intensive Care Unit, Brooke Army Medical Center.

Col Shackelford, MC, USAF, is a trauma surgeon, currently serving as the Chief of Performance Improvement, Joint Trauma System, San Antonio, Texas. She is a member of the Committee on TCCC and has previously deployed as the director of the Joint Theater Trauma System.

APPENDIX A: ESCHAROTOMY INCISIONS



The incisions on the extremities are placed along the mid-medial and/ or mid-lateral joint lines. The bold lines indicate the importance of always carrying the incisions across any involved joints. The incisions on the chest are intended to free up a mobile "plate" of tissue to restore adequate chest movement with breathing.

Source: Figure 26.1, p. 379, Chapter 26 (Burns). In: Anonymous, *Emergency War Surgery, 4th United States Revision*. Fort Sam Houston, TX: Office of the Surgeon General, Borden Institute, 2013.

Figure A1. Photograph of a patient undergoing escharotomy of the leg, using electrocautery. The goal is to go through the burned skin into viable tissue (i.e., subcutaneous fat).

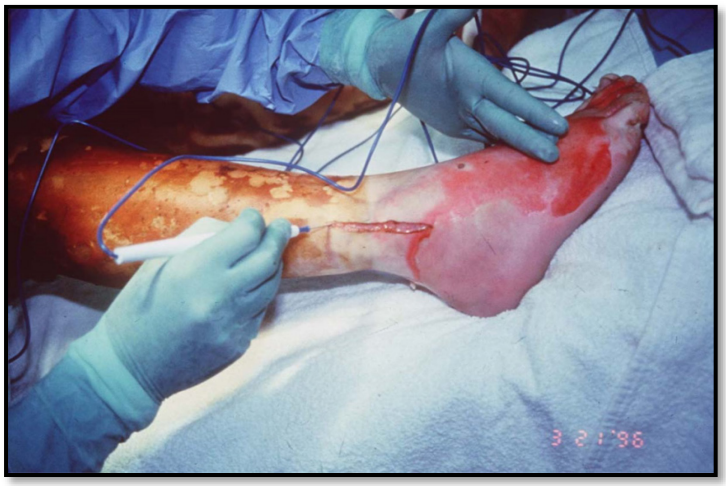


Figure A2. Photograph of a patient undergoing escharotomy of the leg and foot, using a scalpel. When using a scalpel, there may be increased blood loss compared to electrocautery, as shown here.

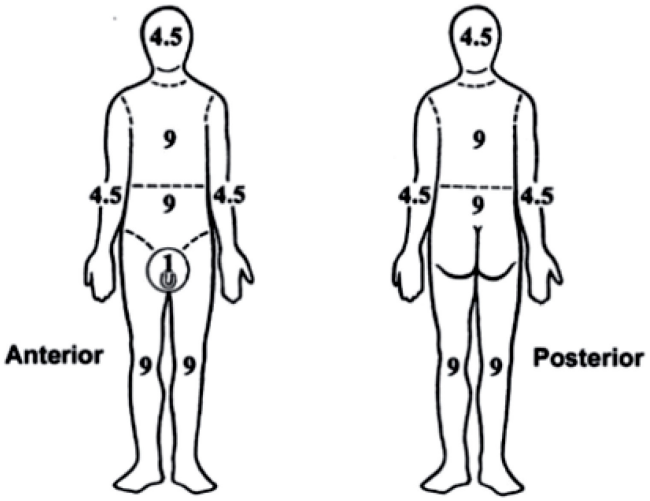
APPENDIX C: RULE OF NINES BURN WOUND CALCULATION



Use this image to calculate the percent of total body surface area (%TBSA) involved by second and third degree burn wounds (do NOT include first degree wounds in this assessment). Example: Second and third degree wounds involving the entire anterior torso and right upper extremity, front and back, would be cover 27% TBSA. If this wound had scattered areas of unburned skin and/or first degree burns, adjust the %TBSA downward. %TBSA is an estimate. Both over- and underestimates have potential negative impacts on a patient's resuscitation.

APPENDIX D: JOINT TRAUMA SYSTEM (JTS) BURN RESUSCITATION FLOW SHEET

Total Fluids:									

APPENDIX E: FLUID & EQUIPMENT PLANNING CONSIDERATIONS

Assumptions: One patient with a 50% total body surface area (TBSA) burn, weighing 80kg, and requiring 4mL/kg/%TBSA for resuscitation the first day (16L), half that the second day (8L), and half that the third day (4L).
Note: For planning purposes only, the Parkland formula of 4mL/kg/%TBSA provides an estimate for the first 24-hour fluid requirements; however, hourly fluid resuscitation should start with the rule of 10s.

Best:

- Fluids: IV fluid (lactated Ringer's solution or Plasma-Lyte) to provide resuscitation for 72 hours (28L)
- Equipment: Portable monitor with capnography; lab capability for serum electrolytes, arterial blood gases, and lactate; Foley catheter with graduated collection system; portable ventilator; portable suction; electrocautery or scapel; oxygen or oxygen concentrator; airway management kit to include endotracheal suction catheter
- Medications: pain medications (refer to *Analgesia, Sedation* CPG)
- Burn-specific dressings: Hibiclens to clean wounds, Silvadene and/or Sulfamylon cream (two 400g jars per patient per day), or silver nylon (Silverlon) dressings
- Nonspecific dressings: roller gauze, torso dressings, tape or stapler
- Hypothermia prevention: sleeping bag or Hypothermia Prevention & Management Kit (HPMK)
- Monitoring: Portable monitor providing continuous vital-signs display; capnography, if intubated; document vital-signs trends, intake and output, GCS, and pain level on a regular basis; burn-resuscitation flow sheet
- Push-pack capability: prepackaged additional 24-hour supplies of fluids, dressings for scenarios >24 hours or >1 patient

Communications: real-time video telemedicine consultation

Better:

- Fluids: IV fluid (lactated Ringer's solution or Plasma-Lyte) to provide resuscitation for 24 hours (16L); oral electrolyte replacement
- Equipment: Blood pressure cuff, stethoscope, pulse oximeter, capnometer, portable ventilator, oxygen or oxygen concentrator, airway management kit to include endotracheal suction catheter
- Graduated container to monitor urine output
- Pain medications
- Nonspecific dressings: roller gauze, torso dressings, tape or stapler
- Hypothermia prevention: sleeping bag/HPMK/ Blizzard Blanket (Blizzard Protection Systems Ltd., http://www.blizzardsurvival.com/)
- Monitoring: Frequent vital signs, examination, fluid input, urine output, flowsheet to document

Communications: telephone; e-mail digital photos

Minimum:

- Fluids: Resuscitation with commercial or improvised electrolyte solution (oral, enteral, rectal)
- Equipment: Blood pressure cuff, stethoscope, pulse oximeter, bag-valve mask with positive end-expiratory pressure (PEEP) valve, airway management kit
- Graduated or improvised graduated container to monitor urine output
- Pain medications
- Clean sheet, any available trauma dressings
- Hypothermia prevention: sleeping bag/emergency blanket/blankets
- Monitoring: Frequent vital signs, examination, fluid input, urine output documented on preprinted or improvised flowsheet

Communications: Telephone.

APPENDIX F: SUMMARY TABLE

Airway	
Best	• Rapid Sequence Intubation • Continuous sedation + airway maintenance and suctioning • O_2 and portable ventilator
Better	• Cricothyroidotomy • Continuous sedation + airway suctioning • O_2 concentrator and portable ventilator
Minimum	• Cricothyroidotomy • Ketamine • Bag-valve-mask with PEEP valve
Assess Burn Size	
Best	• For initial estimate: Rule of 9s • After wounds are cleaned/debrided: re-calculate burn size using Lund-Browder chart
Better	• Same as minimum
Minimum	• For large burns: Rule of 9s • For small burns: Use patient's hand = 1% TBSA
Fluid Resuscitation	
Best	• Use isotonic crystalloid: Lactated Ringer's (LR) or Plasma-Lyte • Starting fluid rate is rule of 10s (TBSA x 10; +100 ml/hr for each 10 kg over 80 kg)
Better	• Oral resuscitation with electrolyte solution (avoid plain water) • Possible for up to 30% TBSA burns • "Coached" drinking on a schedule to meet target fluid rate
Minimum	• Rectal infusion of electrolyte solution • Can infuse up to 500 ml/hr • May use to supplement oral hydration
Teleconsultation	
• Establish contact early • Ventilator management • Measuring burn size • Hemorragic shock + burns	• Burn > 20% TBSA • Electrical burn • Escharotomy needed • Infection
Monitoring	
Vital Signs	
Best	• Portable monitor • Capnography • Document vital signs (VS) and I/O on flow sheet
Better	• BP cuff, stethoscope • Pulse oximetry, Capnography • Document VS and I/O on flow sheet
Minimum	• Blood Pressure (BP) cuff, stethoscope • Pulse oximetry • Document VS on flow sheet
Urine Output	
Best	• Foley catheter, titrate fluids to keep urine output (UO) 30-50 ml/hr • Increase or decrease fluid rate by 25% each hour if UO not at goal
Better	• Collect urine in graduated container • >180 ml every 6 hours is adequate
Minimum	• If unable to measure UOP, adjust fluids to maintain HR <140, good capillary refill, intact mental status • Treat hypotension if needed, but this is a late sign of hypovolemia

Extremity Burns	
Best	• Elevate, Exercise • Monitor pulses hourly, Doppler flow meter • Escharotomy if circumferential 3rd degree burn
Better	• Elevate, Exercise • Monitor pulses hourly • Escharotomy only if unable to palpate distal pulses and evacuation delayed
Minimum	• Elevate, Exercise • Monitor pulses hourly
Pain Management	
Best	• Ketamine infusion • Supplement with IV opioids and midazolam (e.g., Versed), frequent small doses
Better	• Ketamine IV • Supplement with IV opioids and midazolam, frequent small doses
Minimum	• Fentanyl Lozenge • Oral acetaminophen/oxycodone (e.g. Percocet, Endo Pharmaceuticals, http://www.endo.com/)
Infection	
Prevent Infection	
Best	• Clean wound and debride loose dead skin using gauze and Hibiclens in clean water • Apply antimicrobial cream (Silvadene or Sulfamylon), cover with gauze. • Alternative: Apply Silverlon dressings to clean wounds, cover with gauze
Better	• Clean wound and debride loose dead skin using any antibacterial soap in clean water • Apply any available dressing • Optimize wound care and hygiene to extent possible
Minimum	• Cover with clean sheet or dry gauze • Leave blisters intact
Treat Infection	
Best	• If cellulitis (spreading erythema around edge of burn) treat with IV antibiotics (e.g., cefazolin or clindamycin) • If invasive infection with sepsis, foul smell, or burn wound color change, cover gram-positive and gram-negative and Pseudomonas bacteria (e.g. ertapenem + ciprofloxacin)
Better	• Same as minimum
Minimum	• If cellulitis (spreading erythema around edge of burn) or invasive infection, treat with antibiotics. • Any available antibiotic

APPENDIX G: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Catastrophic Non-Survivable Brain Injury (CPG ID: 13)

Useful guidelines to manage casualties with catastrophic, non-survivable brain injury at Role 2 and Role 3 facilities.

BACKGROUND

Catastrophic brain injury, for the purpose of this guideline, is defined as any brain injury that is expected after imaging evaluation and /or clinical exam to result in the permanent loss of all brain function above the brain stem level.

NOTE: For patients with potentially survivable but severe Traumatic Brain Injury (TBI), refer to Joint Trauma System CPG, *Neurosurgery and Severe Head Injury, 02 Mar 2017*.

1. The intent of this guideline is to provide clinically useful recommendations which will allow providers at all roles of care who encounter these injuries to optimize the opportunity for these casualties to be evacuated safely and appropriately to the next level of care.

2. It is not the purpose of this guideline to address the complexities of brain death determination, or at what role of care and by what types of providers this determination should be made.

3. If appropriately resuscitated and hemodynamically normalized, these patients are more likely to be re-united with their families at Role 4 facilities. Additionally, evacuation from a combat theater of operations preserves the potential to honor the expressed intent of a patient to participate as an organ donor. Experience at Landstuhl Regional Medical Center between 2003 and 2013 demonstrated this opportunity to be on par with higher performing centers in CONUS. (Publication in draft, J. Oh, personal communication, 05 Aug 2016)

Catastrophic brain injury is associated with profound physiologic alterations that result in diffuse vascular regulatory disturbances and widespread cellular injury.[1, 2] Severe alterations in metabolism,[3-5] endocrine function,[6-9] immunology[10] and coagulopathy[11-17] also commonly manifest. These disturbances frequently lead to multiorgan system failure, cardiovascular collapse and asystole in up to 60% of patients if not appropriately managed.[3]

It is known from animal studies that this cardiovascular deterioration is associated with impaired oxygen utilization, a shift from aerobic to anaerobic metabolism, a depletion of glycogen and myocardial high-energy stores, and the accumulation of lactate.[3,5,9] This irregular metabolism has been associated with low levels of triiodothyronine (T3), thyroxin (T4), and to a lesser extent cortisol and insulin.[6-9] Therapeutic replacement with T3 has been associated with complete reversal of anaerobic metabolism and subsequent stabilization of cardiac function when applied to human brain dead subjects.[6,7] In addition, the use of T3 and similar thyroid replacement preparations have been associated with significant improvements in cardiovascular status, reductions in inotropic support, and decreases in donors lost from cardiac instability.[5, 18-20] The etiology of this functional “hypothyroid state” is poorly understood, but may be a result of lower than normal thyroid stimulating hormone levels caused by the irreversible damage to the hypothalamus and pituitary from ischemia.[21] Another explanation is a decrease in the peripheral conversion of T4 to its more potent analogue T3, similar to the euthyroid sick syndrome. It should be noted that evidence which validates the efficacy of hormonal replacement in this population of patients is not conclusive.[22, 23] While this subject matter continues to be evaluated it should be recognized that early, effective, conventional critical care management is the therapeutic mainstay in these patients.[24]

TREATMENT

The clinical management of catastrophic brain injury is focused on hemodynamic stabilization. This consists of three aspects:

1. Early identification of the severity of injury, as severity of the TBI correlates with deficiencies in the pituitary adrenal axis, leading to hemodynamic instability.[25]
2. Intensive care management to achieve hemodynamic stability based on degree of TBI and associated injuries.[26]
3. Resuscitation with fluids and blood products, early use of vasopressors and consideration for endocrine/hormone therapy in patients with refractory hemodynamic instability.

Vasopressors such as norepinephrine should be utilized if the mean arterial pressure (MAP) remains less than 70 mmHg despite adequate fluid resuscitation. (See Appendix A.) In patients whom Diabetes Insipidus (DI) is suspected, consider adding a vasopressin drip to norepinephrine after initial treatment with DDAVP. (See Appendix A and Appendix B treatment of DI). In casualties with catastrophic head injury who require more than a single vasopressor to maintain a systolic blood pressure of 100 mmHg or have evidence of DI, strong consideration should be given for addressing the endocrine abnormalities associated with these injuries that can contribute to ongoing hemodynamic instability. (See Appendix B.)[25-29] Adjuncts shown to assist with hemodynamic stability include stress dose steroids, IV insulin, and replacement of thyroid hormone.

These adjuncts are:

1. 1 ampule 50% dextrose IV
2. 2 g solumedrol IV
3. 20 units regular insulin IV
4. 20 micrograms of thyroid hormone (T4) IV, if available

This is given as an initial bolus followed by a continuous infusion of 10 mcg/hr of T4, if it is available.

An appropriately aggressive approach should also stress early identification and management of catastrophic brain injury-related complications such as:

1. Disseminated intravascular coagulation (DIC)
2. Diabetes Insipidus (DI)
3. Neurogenic pulmonary edema (NPE)
4. Hypothermia
5. Cardiac arrhythmias

See Appendix C for management points on each.

TRANSFUSIONS CONSIDERATIONS

The use of blood products for these patients is a complex issue involving the proper use of limited resources in theater and the paucity of evidence-based recommendations on this topic. If the patient responds hemodynamically to the previous interventions and appears stable after the initial insult, a reasonably aggressive approach should be taken to correct coagulopathy rapidly and transfuse PRBCs to a level sufficient to optimize oxygen delivery to tissue and organs. There is little to support optimal hemoglobin in this population, but in general critically ill populations, a target above at least 7g/dL has been recommended.[30] In this patient population, however, goal hemoglobin of 10g/dl has been set for this protocol. (See Appendix A.) Other blood products are used as per standard ICU practice to correct pre-existing traumatic coagulopathy or disseminated intravascular coagulation generated by the release of tissue factor from necrotic brain tissue. An International Normalized Ration (INR)<1.5 and platelet count >50,000 should be considered until evacuation occurs.[31]

DETERMINING FUTILITY AND THE APPROPRIATENESS OF TRANSPORT

RESPONSIVE

Within the context of a catastrophic, non-survivable brain injury, if the patient responds to initial resuscitation and treatment and achieves clinical stability, transport to the next higher role of care should be considered. In these circumstances, aggressive effort should be made to re-unite the service member with family at the Role 4 facility. As a secondary priority to be considered only in these otherwise futile situations, service members may also be evaluated for potential organ donation at the Role 4 facility.

NON RESPONSIVE

Within the context of a catastrophic, non-survivable brain injury, if the patient does not respond to initial aggressive resuscitation, continued further efforts should be guided by a combination of clinical judgment and battlefield effects, including: resources available at the current role of care facility (critical care personnel, equipment, and supply resources), other critically injured patients requiring immediate attention, potential for further casualties from active troop contact, and availability and capacity of evacuation to next higher role of care.

The medical evacuation clinical and operational leadership should be engaged early in these circumstances. Clinical discussion and decisions regarding stability for transport should occur between the trauma team and the flight team. The clinical team should also inform medical operations leadership who will be able to provide information about evolving battlefield effects affecting the availability and capacity of transport.

If the patient cannot be clinically stabilized or battlefield effects otherwise preclude transport, no further efforts should be pursued and withdrawal of support with dignity and with comfort measures is the most respectful and appropriate course of action. Providers presented with these patients are always encouraged to discuss patient care with colleagues and medical leadership at their location to achieve a clinical consensus in these very difficult situations. When available and appropriate, they are also encouraged to communicate with trauma providers at the next higher role of care to achieve consensus on the plan to transport or not to transport. These situations are fortunately not common, but constitute the most challenging of clinical and ethical management dilemmas that one can face while deployed.

PERFORMANCE IMPROVEMENT MEASURES

POPULATION OF INTEREST

All patients with traumatic brain injury with head AIS > 3 and Role 3 or Role 4 discharge GCS=3 and death within 30 days.

INTENT (EXPECTED OUTCOMES)

1. Safely evacuate patients in the population of interest to Role 4.
2. Patients with catastrophic brain injury receive medical management according to the CPG.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who have a documented neurosurgery consultation.
2. Number and percentage of patients diagnosed with brain death at Role 4 who are organ donors.

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for Performance Improvement (PI) monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed. The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

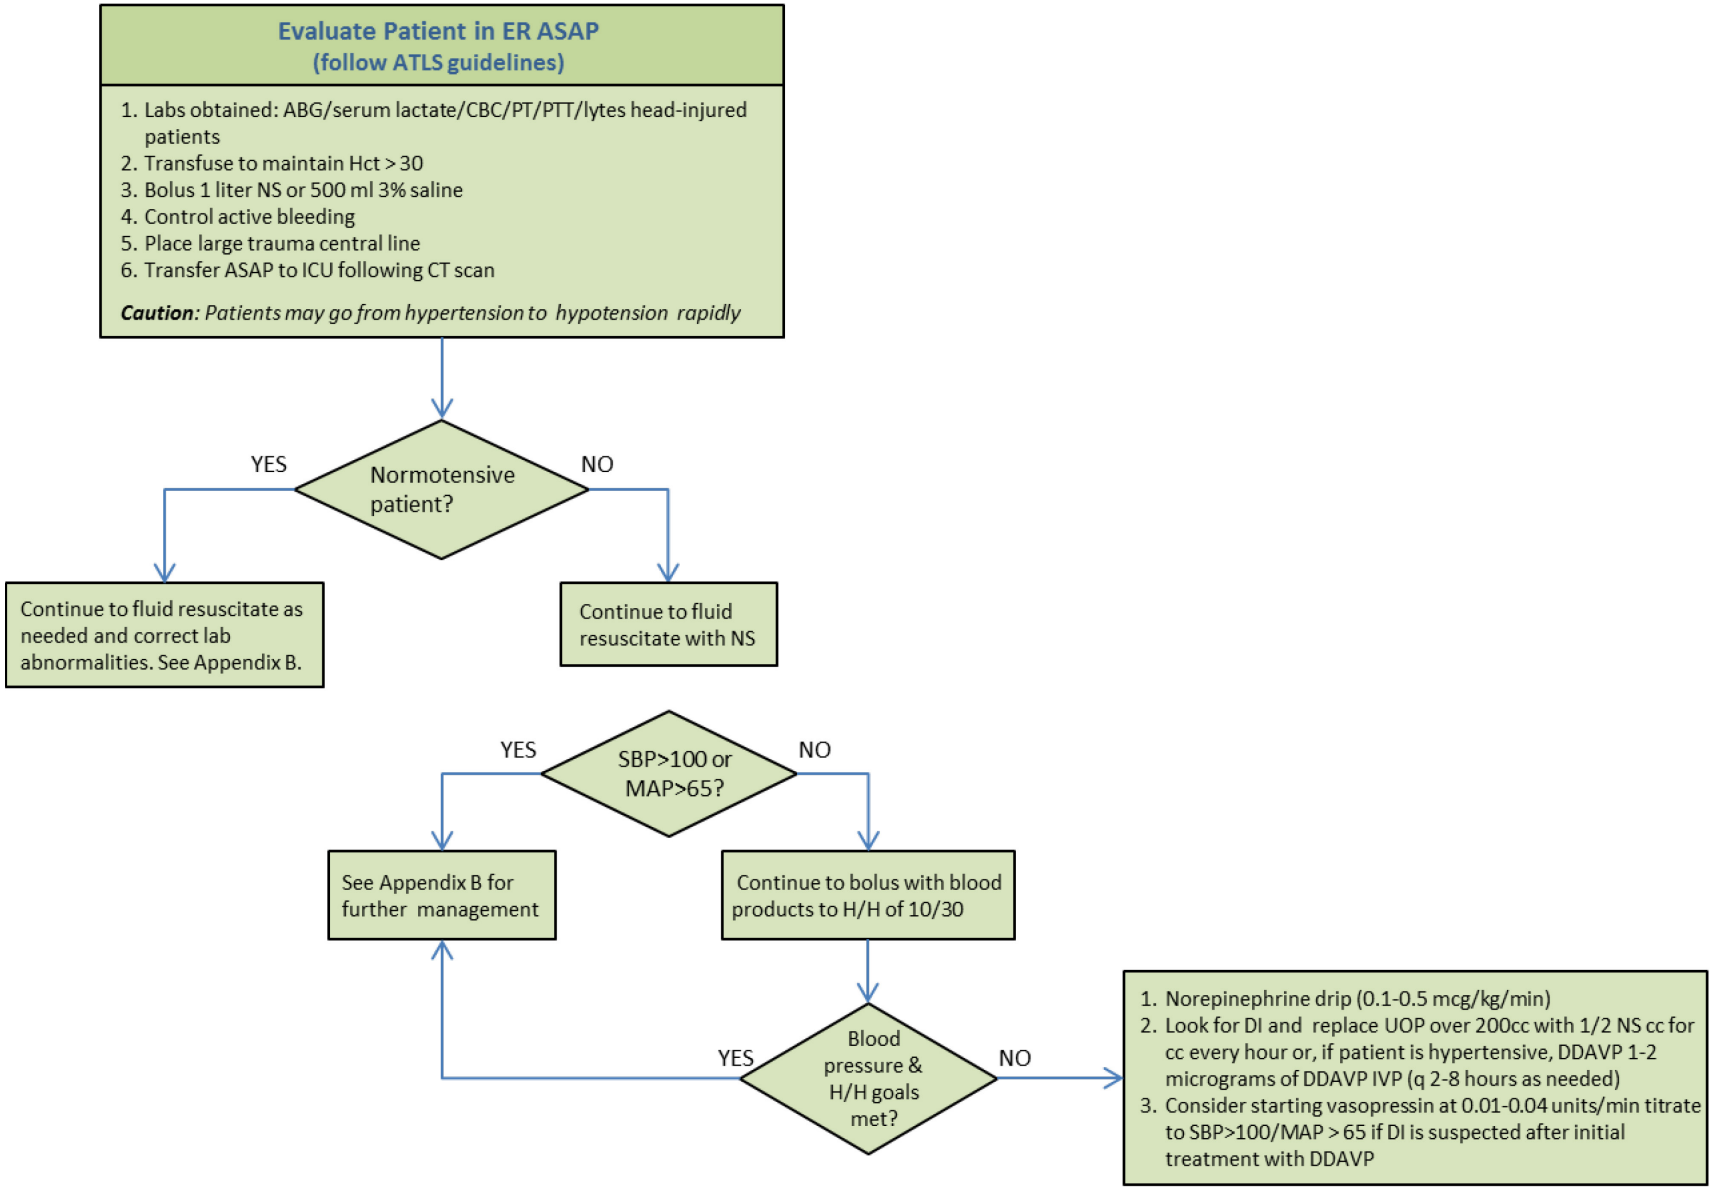
APPENDIX A: CATASTROPHIC BRAIN INJURY RESUSCITATION MANAGEMENT FOR PERSISTENT HYPOTENSION



Evaluate Patient in ER ASAP
(follow ATLS guidelines)
1. Labs obtained: ABG/serum lactate/CBC/PT/PTT/lytes head-injured patients
2. Transfuse to maintain Hct > 30
3. Bolus 1 liter NS or 500 ml 3% saline
4. Control active bleeding
5. Place large trauma central line
6. Transfer ASAP to ICU following CT scan
Caution: Patients may go from hypertension to hypotension rapidly
Normotensive patient?
YES
NO
Continue to fluid resuscitate as needed and correct lab abnormalities. See Appendix B.
Continue to fluid resuscitate with NS
SBP>100 or MAP>65?
YES
NO
See Appendix B for further management
Continue to bolus with blood products to H/H of 10/30
Blood pressure & H/H goals met?
YES
NO
1. Norepinephrine drip (0.1-0.5 mcg/kg/min)
2. Look for DI and replace UOP over 200cc with 1/2 NS cc for cc every hour or, if patient is hypertensive, DDAVP 1-2 micrograms of DDAVP IVP (q 2-8 hours as needed)
3. Consider starting vasopressin at 0.01-0.04 units/min titrate to SBP>100/MAP > 65 if DI is suspected after initial treatment with DDAVP

APPENDIX B: MANAGEMENT OF CATASTROPHIC BRAIN INJURY

1. Disseminated Intravascular Coagulation (DIC)

Begin correcting any coagulation lab abnormalities (thrombocytopenia, increased INR) early, before clinical DIC.

2. Diabetes Insipidus (DI)

- If patient is normotensive, serum sodium > 150 and Urinary Output (UOP) > 600cc/hr, give 1-2 micrograms of DDAVP IVP (q 2-8 hours as needed)
- Replace UOP cc for cc with 1/2 NS q hour for UOP > 200 (example: for UOP of 1000cc replace with 800cc of 1/2 NS).
- If patient's serum sodium > 150 and UOP > 300cc/hr, replace UOP cc for cc with 1/2 NS q hour for UOP > 200cc.
- If patient is hypotensive, then use protocol in Appendix A, and consider adding a vasopressin drip if DI is suspected.

Pitfalls: Assuming high UOP is from DI, but is really from diuretics and/or Mannitol. Replace diuretic fluid loss with NS or LR if hypotensive. (Another marker of DI: urine specific gravity < 1.005).

3. Tachycardia and Hypertension

This commonly occurs prior to complete herniation and should not be treated. Abrupt fluctuations in blood pressure during the period before and immediately after herniation are common. Aggressive treatment of hypertension will only further exacerbate the hypotension that may follow during the natural physiologic course of the herniation process.

4. Neurogenic Pulmonary Edema

This may occur and results in decreased PaO2; increase ventilator support as needed. With severe problems of oxygenation, utilize increased Positive End Expiratory Pressure (PEEP) and consider advanced ventilator modes such as Airway Pressure Release Ventilation (APRV) or VDR if available. Increasing PEEP, however, can decrease cerebral venous return and should be considered when managing neurogenic pulmonary edema. Similarly, APRV results in permissive hypercapnia, also detrimental to a head injured patient. Once neurogenic edema has been diagnosed, maintaining a low cardiac filling and limiting intravenous fluids to minimize pulmonary edema would be ideal, however, it must be done while balancing of needs of the other organ systems.

5. Hypokalemia and/or Hyperglycemia

Use sliding scales as needed.

6. T4 Protocol

Many patients have a T-3/T-4 deficiency and require additional thyroxin. Start patients on thyroxin protocol if thyroxine is available in patients with severe TBI that are continually hypotensive despite adequate fluid resuscitation and high dose pressors. (Appendix C: T-4 Replacement Protocol) Be aware that potassium will likely need to be aggressively replaced once thyroxin is started.

7. Cardiac Arrest

Follow ACLS code guidelines.

APPENDIX C: T-4 REPLACEMENT PROTOCOL

PRETREATMENT

1. Fluid resuscitate to predefined endpoints (CVP > 7, SBP > 100)
2. Give blood to achieve an H&H above 10 and 30
3. Correct electrolyte imbalances

PREREQUISITE

Patient is requiring a combined vasopressor need greater than 15 mcg (all VP added) to maintain a systolic pressure of 100 after the pre-treatment is completed or becomes hemodynamically unstable.

T-4 PROTOCOL

- Administer IV boluses of the following in rapid succession:
  - 1 Amp of 50% Dextrose
  - 2 gm of Solumedrol
  - 20 units regular insulin
  - 20 mcg Thyroxin (T-4)
- Start a drip of 200 mcg T-4 in 500cc Normal Saline (0.4mcg/cc). Administer at 25cc (10mcg) per hour initially. Reduce levels of other vasopressors as much as possible and then adjust T-4 as necessary to maintain desired pressure.
  - Donors > 100 lbs give above dose
  - Donors 50-75 lbs. give 13cc = 5.2 mcg/hr
  - Donors 75-100 lbs. give 19cc = 7.6 mcg/hr
- After 30 to 60 minutes, patients may become tachycardic with an increase in temperature and blood pressure.

  Monitor K+ levels carefully. The only perceived complication of T-4 identified to this point is an unusually high K+ requirement in some cases.

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

GOAL

The *Cervical and Thoracolumbar Spine Injury Evaluation, Transport, and Surgery CPG* delivers updated, accurate guidance to the deployed provider in order to afford the best care to patients who suffer a spinal column or spinal cord injury. This requires constant re-evaluation of the literature, both military and civilian, in addition to reviewing the lessons learned from past and present deployments. Review of these sources drives evidenced-based changes in treatment and triage algorithms, while providing updates on injury classification and current mechanisms of injury.

The authors provide key recommendations for each section.[1] It should be noted that while there may be strong evidence in the civilian literature for managing certain aspects of trauma, not all of these recommendations translate into a combat-trauma setting and so the account for the resource restricted environment of the deployed setting.

BACKGROUND

Injury to the spinal column or spinal cord occurs in approximately 5.5% of evacuated battle casualties and are among the most disabling conditions wounded service members face.[2,3] Spine injuries in theater occur through a variety of battle-related and nonbattle related mechanisms.[2,4,5] In a review of the Joint Theater Trauma Registry (now the DoD Trauma Registry) from 2001-2009, Blair reported the characteristics of 598 American service members who sustained spine injuries during Operation Iraqi Freedom and Operation Enduring Freedom.[2] In this population, 502 (84%) patients experienced 1,834 battle-related spine injuries. The remaining 96 (16%) service members sustained 267 nonbattle-related injuries.[2] From a mechanistic perspective, most battle injuries occur from explosions (66.7%) or gunshot wounds (17%) while nonbattle injuries most frequently result from motor vehicle accidents (54%) or falls (30.2%).[2] Additionally, patients with battle related spine injuries have significantly higher Injury Severity Scores (ISS), present more frequently with noncontiguous spinal fractures and are more likely to require operative intervention.[2,5] Despite these differences, the rate and severity of underlying spinal cord injury appears similar between groups. Blair reported an 18.1% incidence of spinal cord injury in patients with battle-related injuries compared to a 13.5% incidence in the nonbattle-related group. Of patients with neurologic deficits, approximately 45% from each group presented with a complete deficit.[2] In a separate review of the same 598 records, Blair reported 66% of injuries occurred due to blunt trauma, while 28% resulted from penetrating injuries and 5% experienced a combined blunt and penetrating mechanism.[4] Patients sustaining penetrating injury were more likely to experience spinal cord injury than those with blunt force mechanisms (38% vs. 10% $p<.0001$).[4]

The timing and location of surgical intervention has also been a point of debate both in civilian and military settings.[6-10] The scarcity of data defining the optimal setting for surgical intervention when the injury occurs in a combat zone adds further challenges. The goal of decompressing and stabilizing the spine/spinal cord injury must be weighed by operational and logistical considerations in addition to the ability of the deployed spine surgeon.

In general, spine trauma patients may be placed into one of 3 clinical categories:

1. Patients with complete spinal cord injury.
2. Patients with an incomplete spinal cord injury
3. Patients with a spine fracture but normal neurological function.

In regards to the timing of surgery, an incomplete injury from a non-penetrating mechanism is often the most challenging in the decision-making process as these patients are the ones most likely to benefit from early surgical intervention in terms of neurological recovery.[5,9]

CLINICAL & RADIOGRAPHIC EVALUATION

KEY RECOMMENDATIONS

1. Document the patient's neurologic status via the American Spinal Injury Association (ASIA) Examination. Alternatively, the Combat Neuro Exam can be used. (**Level III**)

2. Computerized tomography (CT) is the recommended means to radiographically assess for bony spinal injuries. (**Level I**)

3. Plain films can be used to radiographically assess the bony spine if CT is not reasonably available, but caution should be used in removing cervical stabilization without CT imaging. (**Level III**)

4. CT Angiography (CTA) is recommended for any patient with a suspected craniocervical vascular injury. (**Level II**)

5. Given the limited availability of MRI at echelons lower than Role 4, CT myelography may assist in the evaluation and workup of patients with spinal cord injuries in theater if the required resources are available. (**Level III**)

6. Cervical collars should be placed on all patients with symptoms correlating to a cervical spine injury or in accordance with the Canadian C-spine Rule. (**Level III**)

7. Clearance of a C-spine can be done via a clinical exam, radiographic studies, or a combination of the two depending on the neurological status of the patient. Document the clearance of the C-spine (**Level II**)

NEUROLOGIC EXAM

Every effort must be made to document an accurate and thorough neurological examination, especially when surgery or aeromedical transport is planned. The quality of the examination can be degraded by patient's mental status, effort and degree of cooperation, medication effect including sedatives, the presence of an airway adjunct or endotracheal tube, or the presence of other injuries. Failure to perform and document a neurological exam has been the most common source of discrepancy between serial neurological examination findings, especially between levels of care.

A thorough neurologic exam should include:

- Motor exam of the 10 ASIA key motor groups (Appendix A).
- Sensory examination (pin prick and light touch) using ASIA dermatomal standards.
- Digital rectal exam that assesses voluntary anal sphincter contraction strength, pinprick sensation, resting tone and bulbocavernosus reflex (BCR).

- Normal and pathological reflex testing such as biceps, triceps, brachioradialis, knee, and ankle jerk responses as well as presence/absence of Babinski reflex and Hoffman's signs, or evidence of spinal cord injury patterns, including Central Cord Syndrome, Brown-Sequard Syndrome, etc.

In patients with suspected spinal column injury, with or without neurologic deficit upon presentation, frequent repetition and surveillance of the neurologic examination (focusing upon motor and sensory performance) is imperative. It is recommended to use Appendix A: ASIA Worksheet and attach to the patient's chart.

Alternatively, the *Combat Neuro Exam* is a simpler documentation tool than the *ASIA Worksheet* and may be more amenable to non-spine specialists to complete. (See Appendix B: Combat Neuro Exam.) This note addresses the minimal elements of a complete neurological exam for a patient with significant spinal column injury. Fill out and attach to the patient's chart.

RADIOGRAPHIC ASSESSMENT

In the assessment of the patient with possible spinal injury, plain radiography has been superseded by axial CT with sagittal and coronal reconstruction where available.[11] If CT is not available and evacuation to a higher level of care will not occur in a timely fashion, then plain radiographs will suffice for clinical decision.

Often, polytrauma patients will undergo a protocoled study involving a CT angiography of the neck, with follow-through of the chest, abdomen and pelvis, which adequately assesses the entire spinal axis for osseous as well as craniocervical vascular compromise. For less severely injured patients not warranting such a study, clinical suspicion should guide the decision to obtain imaging. A low threshold to obtain a CTA should be maintained, particularly in those with a documented cervical spinal fracture, or positive screening criteria for blunt cerebrovascular injury (BCVI); see Appendix C: Expanded Screening Criteria for Blunt Cerebrovascular Injury).[12]

In instances of spinal injury with incomplete deficits of the spinal cord, conus medullaris or cauda equina, particularly when those deficits are progressive, consideration should be given to performance of CT myelography (See Appendix D: Adaptation from Omnipaque™ (iohexol) package insert). This would allow for the most rapid diagnosis and potential opportunity for decompression when faced with an incomplete or progressive deficit.

WHEN TO USE A RIGID CERVICAL COLLAR

Patients who have sustained injuries through the following mechanisms should have a rigid cervical collar if available, or some other form of cervical stabilization placed in the prehospital environment if the tactical situation allows:

- Trauma resulting in loss of consciousness or even the question of loss of consciousness due to any form of head injury.
- Trauma resulting in temporary amnesia/loss of consciousness.
- Major explosive or blast injury.
- Mechanism that produces a violent impact on the head, neck, torso or pelvis.

- Mechanism that creates sudden acceleration/deceleration or lateral bending forces on the neck or torso.
- Fall from height (vs. fall from standing).
- Ejection or fall from any motorized vehicle.
- Vehicle rollover.

The Canadian C-Spine Rule was developed to reduce unnecessary imaging of the cervical spine in low risk patients.[13] The Rule was subsequently validated and applied to the prehospital setting.[14]
The Rule comprises the following three main questions:

1. Is there any high-risk factor present that mandates radiography (i.e. age ≥65 years, dangerous mechanism, or paresthesias in extremities)?

2. Is there any low-risk factor present that allows safe assessment of range of motion (i.e., simple rear-end motor vehicle collision, sitting position in ED, ambulatory at any time since injury, delayed onset of neck pain, or absence of midline C-spine tenderness)?

3. Is the patient able to actively rotate neck 45° to the left and right?

When combined, the Canadian C-Spine Rule has a 100% sensitivity for ruling out clinically important cervical injuries.[13] While combat injury mechanisms generally fall within the definition of a "dangerous mechanism" as listed above, dismounted Improvised Explosive Device (IED) blast injuries without associated head trauma have been found to have a low incidence of cervical spine fractures.[14] Thus, it warrants consideration that injured patients without neurologic symptoms, who are ambulatory, and who have full painless range of motion of the cervical spine may not require prehospital cervical collar placement.[14]

Any patient complaining of neck pain or displaying neurological impairment following a trauma should have a cervical stabilization performed and maintained until the cervical spine has been "cleared" by a qualified provider.[15,16] Removal of the collar may be safely performed without further radiographic imaging if the answers to the Canadian C-Spine Rule are "No" to the first question and "Yes to questions 2 and 3.

In general, patients with penetrating cervical injury from an explosive mechanism should have a cervical collar placed if possible. However, patients with isolated penetrating cervical injury who are conscious and have no neurologic signs should not have a cervical collar placed in the prehospital environment. When a blunt mechanism is combined with a penetrating injury, the cervical collar is an important protection until an unstable spinal injury is ruled out. All providers must be aware that the collar may hide other injuries as well as and developing pathology such as expanding hematoma. Patients with isolated penetrating brain injury do not require a cervical stabilization unless the trajectory suggests cervical spine involvement.[17] On the battlefield, preservation of the life of the casualty and medic are of paramount importance. In these circumstances, evacuation to a more secure area takes precedence over spine immobilization.

If a patient has indications for cervical collar placement, and one had not been placed in the prehospital environment for whatever reason, the collar should be placed at the earliest opportunity. unless cervical clearance has been clearly documented in the record or directly communicated to the receiving treatment team, a rigid cervical collar should be placed at each transition in care from downrange and

maintained until it is officially cleared by the receiving providers. This highlights the need for clear and consistent communication along the echelons of care.

CERVICAL SPINE CLEARANCE ALGORITHMS

Any patient with a suspected cervical spine injury and a neurologic deficit should have a cervical collar in place, and should be referred immediately for neurosurgical or orthopedic spine consultation and imaging. All other patients who have indications for prehospital cervical collar placement as detailed above with the Canadian C-Spine Rule should undergo cervical spine clearance by the appropriate algorithm. There are separate algorithms for reliable (Appendix E) and unreliable (Appendix F) patients. Unreliable patients are those who cannot adequately communicate, have a decreased level of consciousness (GCS<15), or have a significant distracting injury. However, controversy exists about the clinical importance of distracting injuries.

Significant distracting injury is technically defined as any injury, which is so painful that it may obscure the patient's ability to notice pain in their neck. The treating physician makes the final determination whether a certain injury is distracting enough to render a patient unreliable and require clearance via the unreliable patient algorithm. The rate of missed injury in the presence of a distracting injury is above 12%, but has not been shown to be significantly higher than in patients without distracting injuries.[18,19] However, if uncertain, err on the side of caution and consider the injury distracting and proceed accordingly. Clearing the C-spine in this scenario requires good communication with the next echelon of care (Appendix G: Cervical Spine Clearance Status) or defer to that level of care for clearance.

See Appendix E and Appendix F for protocol diagrams. If possible, the cervical spine should be cleared and the collar removed within 24 hours of collar placement. If the clinical scenario requires that the collar remain in place more than 24 hours, stiff extrication collars should be replaced with collars designed for long-term immobilization that provide greater padding and decubitus ulcer prevention.

CERVICAL SPINE CLEARANCE IN THE OBTUNDED PATIENT

Cervical spine clearance in the obtunded patient is highly controversial and presents additional challenges to the clinician, especially in the combat environment.[15,17,20] Obtunded patients with a concerning mechanism of injury should undergo CT of the spine with fine cuts and multi-planar reconstructed images (3 mm axial, 3 mm coronal and 2 mm sagittal views). If CT is unavailable or unobtainable, full C-Spine plain radiographs (adequate AP, lateral and odontoid) should be performed.[21] Flexion/extension radiography should not be performed in a patient who cannot be simultaneously examined for the development of neurological signs or symptoms. Ultimately, clearance of the cervical spine in the obtunded patient should be left to clinical decision making of the highest level of care the patient is evacuated to who will be providing their longer term care.

For the obtunded patient with negative imaging, the incidence of significant cervical instability is low. It has generally been accepted that occult ligamentous injury is only cleared through a reliable clinical examination with a cooperative, extubated patient or magnetic resonance imaging (MRI). However, recent literature suggests that a high quality negative CT scan may be enough to remove the cervical collar.[22] This protocol has become the new standard to follow in several high-level acute civilian trauma centers and supports the guideline to forego an MRI as a requirement to clear an obtunded patient, per the *Eastern Association for the Surgery of Trauma Practice Management Guideline*.[22]

"[I]n obtunded adult blunt trauma patients, cervical collars should be removed after a negative high-quality C-spine CT result alone. This recommendation is based on the finding that there is a worst-case 9% cumulative literature incidence of stable injuries and a 91% negative predictive value of no injury, after coupling a negative high-quality C-spine CT result with 1.5-T MRI, upright x-ray series, flexion-extension CT, and/or clinical follow-up. Similarly, there is a best-case 0% cumulative literature incidence of unstable C-spine injuries after negative initial imaging result with a high-quality C-spine CT."

As such, with a high quality CT scan negative for fractures, this method of clearance may be utilized in patients who have arrived at their definitive level of care.

There is risk for significant neck movements in obtunded patients while transiting through the aeromedical evacuation system, so it is recommended that they remain with cervical spine immobilization until arrival at their definitive level of care. The incidence of occipital skin breakdown has decreased with the utilization of collars with greater padding (e.g., Miami-J with Occian back) and increased trauma system awareness of this potential complication.

The clinical decision to definitively clear the cervical spine without exclusion of ligamentous injury by either a reliable clinical examination or a MRI should be left to the level of care providing definitive treatment to the patient. Historically, given the challenges and multiple hand-offs inherent to echeloned care, a "2 out of 3" rule for cervical clearance in the obtunded patient has been Landstuhl Regional Medical Center/Role 4 policy since 2011. This rule requires negative results of 2 of 3 modalities (CT, MRI, clinical exam) prior to removing rigid cervical collars in obtunded patients. Given the low, but non-zero, incidence of significant cervical injury missed on standard 3-plane CT scan, it is recommended that when applying the 2 out of 3 rule, that the obtunded patient be transitioned from the traditional rigid collars to a memory foam enhanced rigid collar if available (i.e. Miami-J with Occian back) until either a reliable clinical examination or MRI can be obtained.[22-25] This method helps to decrease the risk of an occipital decubitus ulcer in those patients with a low likelihood of cervical spine injury who are still in transport and have not yet arrived at their level of definitive care.

Determination of when to image the whole spine (occiput to sacrum) versus selective imaging is based on the mechanism of injury, the physical/neurological exam, as well as the mental status of the patient. Patients who have one identifiable fracture in the spine should have their entire spine imaged. Certain mechanisms of injury, such as a mounted blast, should also warrant imaging of the whole spine.

CERVICAL SPINE CLEARANCE DOCUMENTATION

It is recommended that the JTS Cervical Spine Clearance Status Sheet (Appendix G) or Trauma Resuscitation Record (DD Form 3019) be used for documenting the cervical spine evaluation and clearance status. This comprehensive worksheet includes indications for clearance, exam, imaging studies, and final clearance status. It is intended to bring together all cervical spine information onto one sheet of paper and was designed to improve both the completeness and ease of documentation.

PATIENTS UNABLE TO TRANSFER FROM THEATER

The optimal management of host nationals and others unable to transfer is problematic in the austere environment. The availability to obtain CT or transfer the patient to a facility with CT can make spine evaluation and clearance challenging, with reliance on plain radiographs and physical examination. Sound clinical judgment, remote consultation with a spine surgeon (if available), as well as consultation with theater rules of eligibility are of benefit to decision making.

TRANSPORTING PATIENTS WITH SPINAL INJURIES

KEY RECOMMENDATIONS

1. Use a cervical spine immobilization for transport of patients with cervical spine injuries that have not been previously cleared. (**Level II**)

2. Consider the use of a vacuum spine board when available for the transport of unstable thoracolumbar fractures. (**Level III**)

The recommendations below apply to fixed wing transport of patients, with the following exception being applicable to all mechanisms of transport: The majority of patients with cervical spine injuries should be transported using semi-rigid orthotic such as an Aspen or Miami-J collar (if available).

Clinical scenarios may arise wherein halo immobilization may be suitable. Halo fixation is the most rigid and stable form of external cervical spine fixation.[26] Prior to approving the patient for transport, the team leader must ensure halo removal tools are secured to vest in case there is a need for emergent removal to obtain airway or perform CPR. Additionally, the sending team should educate the transport team how to properly remove the halo if needed. It is not recommended that patients be transported via air or ground in cervical traction as the risk of excessive traction weight transfer associated with vehicular movement, G-forces during takeoff and landing, as well as turbulence can result in further injury.

If the patient has a thoracolumbar fracture that is unstable, then he/she should be transported by the Critical Care Air Transport Team (CCATT) using either a vacuum spine board (VSB) or a standard NATO litter preferably with a memory foam pad to help mitigate pressure sores from Role 2 to Role 3 and beyond if available. Depending on the injury, either of these options can provide sufficient stability to patients with thoracolumbar fractures.[27-29] One small study suggested that pressure ulcer development might be decreased with use of VSB when compared to traditional long spine board.[30]

A thoracolumbosacral orthosis (TLSO) should not be worn during the transport process. This is unnecessary and increases the risk of pressure sores. Prior to transport, the spine surgeon and transportation team should agree upon suitability of VSB versus standard NATO litter. The VSB protocol requires that the VSB be deflated and re-inflated periodically to reduce the risk of pressure sores during the transport process. Logrolling in a VSB without “release of vacuum” does not significantly reduce skin pressure. Additionally, pre-transported skin integrity should be documented and care must be given to padding and pressure reduction maneuvers of the occiput and heels. Once cruising in smooth flight is accomplished, it would be reasonable to release the vacuum until either descent or turbulence is encountered. At a minimum, the VSB pressure should be checked every half hour, smoothed, and re-pressurized every hour, and every two hours the team should release straps and logroll patient (holding patient in appropriate alignment) and provide adequate time for relief of pressure points as part of their normal turning schedule. If the patient is on “spine precautions” due to an unstable cervical or thoracolumbar fracture, the bed should be placed in 30 degree of reverse Trendelenburg if possible. If not on “spine precautions,” then the head of bed should be elevated 30 degrees. During transport, all patients should use the sequential compression devices, which are approved for flight.

MEDICAL MANAGEMENT OF SPINAL CORD INJURIES

KEY RECOMMENDATIONS

1. Avoid hypoxemia (SaO2 <90%) and hypotension (SBP<90) for all spinal cord injuries. (**Level III**)
2. Maintain MAP >85 for all spinal cord injuries, with an emphasis on avoiding hypotension. (**Level III**)
3. Steroids are not indicated in the management of combat spinal cord injuries. (**Level I**)
4. Gabapentinoid medication should be considered early for the treatment of neuropathic pain in patients with spinal cord injuries. (**Level II**)
5. Early mechanical and chemoprophylactic measures against deep venous thrombosis (DVT) should be taken in patients with spine and spinal cord injuries. (**Level II**)

Patients who sustain neurologic compromise should have an invasive arterial line for continuous blood pressure monitoring with a goal MAP of 85-90 mmHg for up to seven days following the injury.[15,31] The evidence supporting this goal is mixed, at best, however it is the opinion of the authors that there is a net benefit to maintaining this goal. Regardless, hypotension (SBP < 90 mmHg) and hypoxemia (SaO2 <90%) must be avoided. Acute management of pulmonary dysfunction following traumatic spinal cord injury improves early survival as complications of pulmonary injury are the leading cause of mortality in traumatic spinal cord injury (SCI), specifically in the cervical spine.[32] Vasopressor therapy (in the euvolemic patient) and/or supplemental oxygen are recommended, when necessary, to achieve these goals.[15] Prior to the use of vasopressors, ensure that hypovolemia is addressed through adequate resuscitation and evaluation and control of any bleeding. Vasopressor use in the hypovolemic patient may contribute to additional ischemic loss in other injured tissues.

GABAPENTINOID & NON-GABAPENTINOID MEDICATIONS

Non-gabapentinoid anticonvulsants (carbamazepine, phenytoin, clonazepam, phenobarbital, valproic acid) are not shown to improve or worsen long-term neurological outcomes from acute spinal cord injury.[33] Early administration of the anticonvulsant gabapentin and pregabalin has been shown to have some improvement of motor recovery, pain intensity, and frequency of autonomic dysreflexia.[34-36] Pregabalin and gabapentin are effective for neuropathic pain, depression, and sleep interference.[36] Early (within 24 hours) administration of enteral gabapentin should be considered for spinal cord injury patients in combat.

OTHER INVESTIGATED THERAPIES

The use of other pharmacologic agents such as riluzole, dantrolene, baclofen, naloxone, tamoxifen, and interventions such as hyperbaric oxygen and nitrous oxide do not have sufficient evidence to make a recommendation for use in combat-related spinal cord injury.

HANDLING

While many spinal fractures require the head of bed to be flat prior to surgical correction or external bracing, the bed can usually be placed in 30 degrees reverse Trendelenberg. Logrolling and sacral off-loading can be safely performed in most cases every 2 hours to prevent skin breakdown and to perform

secondary and tertiary assessments. It is incumbent upon the managing provider to better guide positioning management based upon the specific clinical scenario.

CORTICOSTEROIDS

Although the use of methylprednisolone sodium succinate (MSS) 24-hour infusion remains an option for the treatment of acute spinal cord injury within 8 hours of presentation, its utility in the setting of combat-related blunt or penetrating spinal cord injury is NOT recommended due to the lack of benefit and increased complications.[15,37] The primary reasons are on differences in the mechanism of injury (large caliber high velocity projectiles), geographically different and/or austere environments, and concomitant traumatic injuries sustained in combat. The associated open or contaminated wounds of battle casualties with spine or spinal cord injuries are further complicated with steroid administration. Methylprednisolone administration is NOT recommended for any spinal cord injuries sustained in combat.

DVT PROPHYLAXIS REGIMEN

An aggressive DVT prophylaxis regimen should be established early and maintained beyond the evacuation process. Pneumatic compression devices in conjunction with chemoprophylaxis are established treatment standards. Prophylactic dosing of a subcutaneous low molecular weight heparin (LMWH -- e.g. enoxaparin) or FIXED, low-dose unfractionated heparin (UFH) should be initiated as soon as possible but definitely within 72 hours of injury or repair to reduce the risk of thromboembolic events in the acute period after SCI. Given the potential for increased bleeding events with ADJUSTED-dose UFH, this is not recommended for prophylaxis.[38] Early active or passive mobilization of the patient helps to reduce DVT formation and is frequently cited in support of early surgical fixation, when appropriate. Patients who show clinical signs or symptoms of a DVT should undergo further imaging to confirm the diagnosis. If a DVT is present, treatment should be initiated with therapeutic anticoagulation if approved by the spine surgeon. If full anticoagulation is contraindicated, an IVC filter placement should be considered.

OPERATIVE & NONOPERATIVE TREATMENTS

KEY RECOMMENDATIONS

In cases of incomplete spinal cord injury, spinal decompression should be undertaken as soon as it is safe and feasible to do so, including at Role 3 installations if appropriate support and resources are available in theater. (**Level III**)

Taking into account evacuation time, planned staged operations at Role 3 and 4 facilities are an acceptable option in instances where patients present with incomplete injury or worsening neurologic deficit. (**Level III**)

NON-OPERATIVE TREATMENT

In order to proactively guide treatment and logistical decisions, it is imperative that the deployed surgeon be intimately familiar with the operative and non-operative options in their theatre of operation. The actual materials on hand for non-operative management in the deployed setting may be variable, but generally include C-collars, other orthotic braces, and occasionally, halo devices.

For cervical fracture-dislocations, especially those associated with incomplete injury, closed reduction downrange is recommended. In patients with cervical dislocation and spinal cord injury, CT myelogram may represent an alternative advanced imaging modality prior to proceeding with closed reduction. In the civilian literature, MRI data obtained prior to reduction have not been shown to affect the outcome of the closed reduction, provided the patient is awake, neurologically intact and able to provide a reliable examination.[39] Thus closed reduction of cervical fracture-dislocations, even in the absence of an MRI, may represent another area of possible intervention while in-theater.

OPERATIVE TREATMENT

The decision for operative treatment of U.S. and coalition spine fractures in theater is ultimately left to the deployed surgical team, including the spine surgeon (if available) and the Chief of Trauma. Good clinical judgment is a priority in the care of patients with spine and spinal cord injuries in a deployed setting. Surgery that can be delayed safely until the patient arrives to the Role 4 military treatment facility should be delayed. However, there may be some conditions which may benefit from immediate surgery in-theater, including but not limited to:

- incomplete spinal cord injuries
- open cerebrospinal fluid (CSF) leaks
- expected prolonged delay in transport, or
- where an urgent reduction may improve the degree of "root sparing" in a cervical spinal cord injury.

INCOMPLETE INJURIES

The management of incomplete spinal cord injuries in theater remains controversial due to the potential for higher rates of neurologic improvement with early operative intervention weighed against obvious challenges posed by an austere environment. Initial spinal cord injury or subsequent progression can occur via fracture displacement, bone fragment compression, expanding hematoma, spinal cord edema or infarction. In civilian literature, animal studies have demonstrated that immediate decompression of neural elements is associated with a reduction in neurological sequela.[40-44] Several large investigations have demonstrated significant improvement in neurologic outcomes with early surgical intervention in incomplete spinal cord injuries.[6,10,45,46] This information has led many major U.S. trauma centers to adopt a goal of early surgical decompression in cases of incomplete spinal cord injury. There are some data to suggest that it is not the timing of surgery alone that is the key factor, but the extent of decompression.[47] However, these data must be carefully applied to the deployed setting as forward medicine presents unique challenges not experienced in high volume modern trauma centers. In one investigation examining the outcomes of 50 cases of spinal cord injury treated surgically in theater versus those undergoing delayed care at Landstuhl Regional Medical Center, Schoenfeld demonstrated no differences in neurologic recovery between groups.[9] Patients who were treated with surgery in theater had significantly higher rates of postoperative complications (40% vs. 20%) and had higher rates of additional surgical procedures. Though limited by its relatively low case numbers and retrospective nature, this study may challenge the extrapolation of civilian literature to a deployed setting. Given this conflict in civilian and military literature, deployed spine surgeons should carefully weigh the potential for neurologic recovery with available forward resources in cases of incomplete spinal cord injury. Instances of incomplete neurologic deficit with easily addressed compressive pathology, neurologic progression, delayed evacuation or injuries in coalition partners not eligible for evacuation represent times when operative intervention in theater may provide clear benefit to the patient. In these cases,

implants used in theater should be compatible with systems at higher levels of care in case revision surgery is required.

SPINAL INSTRUMENTATION

The decision to perform spinal stabilization in a deployed setting depends, in part, on the presence and sterility of appropriate implants, comfort level of the operative team and availability of sufficient diagnostic imaging modalities. Advocates for early instrumentation argue that stabilizing these injuries minimizes the need for spinal immobilization, improves pulmonary toilet, lowers the risk of venous thromboembolism and may improve analgesia. Yet, these advantages may not fully translate to the deployed population as over half have concomitant extremity or pelvis fracture and/or significant hemodynamic distress.[48] Deployed surgeons may also consider non-instrumented decompressive procedures in cases with incomplete or progressive neurologic deficit and ongoing canal compromise. These simpler cases often place less strain on the deployed operative team and medical logistical system while requiring less operative time and exposure. This decision for early decompressive surgery with delayed stabilization requires careful direct coordination between spine surgeons at Role 3 and 4 facilities. In Schoenfeld's retrospective review of patients who sustained operative spinal injuries in theater this approach resulted in neurologic improvement in 2 of 3 cases.[9]

PENETRATING SPINE INJURIES

KEY RECOMMENDATIONS

1. Consider early surgery in penetrating spinal cord injury for progressive or incomplete neurological deficits in the setting of continued mass effect upon the spinal cord if surgeon and treatment facility capabilities allow.

2. Patients with concomitant hollow-viscus injuries and penetrating spinal cord injuries should be treated with broad-spectrum anti-microbial coverage for 48 hours to 10 days, depending upon the level of contamination of the injury and control of associated any cerebrospinal fluid leak.

SURGICAL INTERVENTION

Spinal cord injuries from penetrating mechanisms are more likely to produce complete neurologic deficit than those sustained through blunt force.[4,49] With penetrating mechanisms, spinal cord injury can occur through direct damage in the projectile tract or via cavitation injury, whereby shock waves imparted on the tissue surrounding the path of the projectile and rapid changes in pressure damage tissue.[50] The two latter forces can produce severe irrecoverable spinal cord injuries, even in cases where the projectile does not penetrate the spinal canal. In these injuries staged debridement of the wound may be required given the cavitary injury to soft tissue. Surgical indications may include progressive neurological deterioration, incomplete deficit (particularly if a missile or fragment is still within the canal) or the presence of a CSF leak. If surgery is undertaken, good dural closure is paramount with an attempt at "water tight" repair. Anterior and oblique entry to the lumbar and lower thoracic spine are at increased risk of infectious complications due to traversal of hollow viscus organs.[51] In these cases the patient's infectious risk and neurological status are key factors in determining the need for and timing of surgical intervention. There is no evidence from the current conflict to support the concept that a complete SCI from a penetrating mechanism has a significant chance of clinical improvement with surgical intervention.

TREATMENT

In 2010, Klimo et al., led a tri-service literature review of articles on penetrating spinal injury sustained in combat and provided treatment recommendations.[52] Based on this review of both military and civilian literature, they concluded that the role of decompression in promoting neurologic recovery remains ambiguous.[52] For an incomplete injury with continued canal compromise, decompression, if attempted, should ideally occur within 24-48 hours. Additionally, persistent and high-flow CSF-cutaneous and pleural fistulae should be surgically treated. The authors recommended consideration of spinal stabilization at the time of initial surgery in cases with associated instability.[52] Because the unique natural histories of these may render typical blunt injury classification systems less applicable, the treatment of these injuries relies largely on clinical decision making of the operative physician.[5,53] In these situations, surgeons should consider: available resources, expertise of the operative team, infectious risks and the patient's neurological status when determining the need for and timing of operative intervention in theater.

CT scans remain the study of choice for penetrating spinal injuries as MRI is typically not as helpful or available in the deployed setting. Additionally, they can be contraindicated given the ferromagnetic activity of the fragment and bullet material.[54] CT myelogram can be considered in patients with occult or persistent CSF leaks that are not easily localized based on exam or plain CT.

Appropriate antibiotic coverage and duration may often prove controversial. In 2011 the Infectious Disease Society and Surgical Infection Society released a joint guideline for the prevention of infection associated with combat-related injuries.[55] This combined statement recommended Cefazolin 2 gm IV q8hrs for 24-72hrs for penetrating spine injuries without evidence of contamination. Fragments passing through contaminated viscus structures such as the esophagus or colon require extended spectrum intravenous anti-microbial coverage of enteric organisms for longer periods of time. Potential antibiotic regimens include Ancef 2g IV q6-8hrs and Metronidzole 500mg IV q8-12hrs; Cetriaxone 2 g IV q24hrs and Metronidazole 500 mg IV q 8-12hrs. Patients with penicillin or cephalosporin allergies may be treated with Vancomycin 1g IV q12hrs + Ciprofloxacin 400 mg IV q8-12hrs. This working group recommended a minimum antibiotic duration of 5 days or until any CSF leak is closed. Steroids should not be considered as therapy for patients with penetrating spinal cord injuries.[56]

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients at risk of or diagnosed with cervical or thoracic spine injury defined as:

- mechanism of injury explosion, fall, or motor vehicle crash;
- head or neck injury with AIS head or neck > 1;
- diagnosis of fracture of vertebral column with spinal cord injury (806), or spinal cord injury without evidence of spinal bone injury (952); and
- less than 1 day between time of injury and arrival at initial medical treatment facility (MTF).

INTENT (EXPECTED OUTCOMES)

1. Patients in population of interest have documented application of cervical collar or any other method for cervical spine stabilization in the prehospital setting or on MTF arrival.

2. Patients with diagnosis of fracture of vertebral column with spinal cord injury (806), or spinal cord injury without evidence of spinal bone injury (952) have a documented neurologic exam to include GCS and completed *ASIA or Combat Neuro Exam worksheet.*

3. Patients in population of interest have the C-spine clearance status documented on the *JTS C-spine Clearance Status sheet* and *Resuscitation Record (DD Form 3019).*

4. Patients with spinal cord injury and abnormal neurologic exam have an arterial line placed within 24 hours of injury or documentation that not indicated.

5. Patient in population of interest who have an unreliable exam due to decreased level of consciousness (GCS < 14) do not have C-spine cleared prior to arrival at definitive level of care.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in population of interest with documented application of cervical collar or any other method for cervical spine stabilization in the prehospital setting or on MTF arrival.

2. Number and percentage of patients with diagnosis of fracture of vertebral column with spinal cord injury (806), or spinal cord injury without evidence of spinal bone injury (952) with documented neurologic exam to include GCS completed *ASIA or Combat Neuro Exam worksheet*.

3. Number and percentage of patients in population of interest with C-spine clearance status documented on the *C-spine Clearance Status sheet* and *Resuscitation Record (DD Form 3019).*

4. Number and percentage of patients with spinal cord injury and abnormal neurologic exam who have an arterial line placed within 24 hours of injury or documentation that not indicated.

5. Number and percentage of patients in population of interest with Role 2 and/or Role 3 discharge GCS < 14 who have a C-collar in place on arrival to Role 3 for host nation patients or Role 4 for coalition patients.

DATA SOURCE

- Patient Record and the *ASIA or Combat Neuro Exam worksheet*
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed. The system review and data analysis will be performed by the JTS Chief and the PI Branch.

REV 04/19

Muscle Function Grading

0 = Total paralysis

1 = Palpable or visible contraction

2 = Active movement, full range of motion (ROM) with gravity eliminated

3 = Active movement, full ROM against gravity

4 = Active movement, full ROM against gravity and moderate resistance in a muscle specific position

5 = (Normal) active movement, full ROM against gravity and full resistance in a functional muscle position expected from an otherwise unimpaired person

NT = Not testable (i.e. due to immobilization, severe pain such that the patient cannot be graded, amputation of limb, or contracture of > 50% of the normal ROM)

0*, 1*, 2*, 3*, 4*, NT* = Non-SCI condition present *a*

Sensory Grading

0 = Absent **1** = Altered, either decreased/impaired sensation or hypersensitivity

2 = Normal **NT** = Not testable

0*, 1*, NT* = Non-SCI condition present *a*

Note: Abnormal motor and sensory scores should be tagged with a '' to indicate an impairment due to a non-SCI condition. The non-SCI condition should be explained in the comments box together with information about how the score is rated for classification purposes (at least normal / not normal for classification).

When to Test Non-Key Muscles:

In a patient with an apparent AIS B classification, non-key muscle functions more than 3 levels below the motor level on each side should be tested to most accurately classify the injury (differentiate between AIS B and C).

Movement	Root level
Shoulder: Flexion, extension, adbuction, adduction, internal and external rotation **Elbow:** Supination	C5
Elbow: Pronation **Wrist:** Flexion	C6
Finger: Flexion at proximal joint, extension **Thumb:** Flexion, extension and abduction in plane of thumb	C7
Finger: Flexion at MCP joint **Thumb:** Opposition, adduction and abduction perpendicular to palm	C8
Finger: Abduction of the index finger	T1
Hip: Adduction	L2
Hip: External rotation	L3
Hip: Extension, abduction, internal rotation **Knee:** Flexion **Ankle:** Inversion and eversion **Toe:** MP and IP extension	L4
Hallux and Toe: DIP and PIP flexion and abduction	L5
Hallux: Adduction	S1

ASIA Impairment Scale (AIS)

A = Complete. No sensory or motor function is preserved in the sacral segments S4-5.

B = Sensory Incomplete. Sensory but not motor function is preserved below the neurological level and includes the sacral segments S4-5 (light touch or pin prick at S4-5 or deep anal pressure) AND no motor function is preserved more than three levels below the motor level on either side of the body.

C = Motor Incomplete. Motor function is preserved at the most caudal sacral segments for voluntary anal contraction (VAC) OR the patient meets the criteria for sensory incomplete status (sensory function preserved at the most caudal sacral segments S4-5 by LT, PP or DAP), and has some sparing of motor function more than three levels below the ipsilateral motor level on either side of the body. (This includes key or non-key muscle functions to determine motor incomplete status.) For AIS C – less than half of key muscle functions below the single NLI have a muscle grade ≥ 3.

D = Motor Incomplete. Motor incomplete status as defined above, with at least half (half or more) of key muscle functions below the single NLI having a muscle grade ≥ 3.

E = Normal. If sensation and motor function as tested with the ISNCSCI are graded as normal in all segments, and the patient had prior deficits, then the AIS grade is E. Someone without an initial SCI does not receive an AIS grade.

Using ND: To document the sensory, motor and NLI levels, the ASIA Impairment Scale grade, and/or the zone of partial preservation (ZPP) when they are unable to be determined based on the examination results.

AMERICAN SPINAL INJURY ASSOCIATION
INTERNATIONAL STANDARDS FOR NEUROLOGICAL CLASSIFICATION OF SPINAL CORD INJURY
INTERNATIONAL SPINAL CORD SOCIETY

Page 2/2

Steps in Classification

The following order is recommended for determining the classification of individuals with SCI.

1. Determine sensory levels for right and left sides.
The sensory level is the most caudal, intact dermatome for both pin prick and light touch sensation.

2. Determine motor levels for right and left sides.
Defined by the lowest key muscle function that has a grade of at least 3 (on supine testing), providing the key muscle functions represented by segments above that level are judged to be intact (graded as a 5).
Note: in regions where there is no myotome to test, the motor level is presumed to be the same as the sensory level, if testable motor function above that level is also normal.

3. Determine the neurological level of injury (NLI).
This refers to the most caudal segment of the cord with intact sensation and antigravity (3 or more) muscle function strength, provided that there is normal (intact) sensory and motor function rostrally respectively.
The NLI is the most cephalad of the sensory and motor levels determined in steps 1 and 2.

4. Determine whether the injury is Complete or Incomplete.
(i.e. absence or presence of sacral sparing)
*If voluntary anal contraction = **No** AND all S4-5 sensory scores = **0***
*AND deep anal pressure = **No**, then injury is **Complete**.*
*Otherwise, injury is **Incomplete**.*

5. Determine ASIA Impairment Scale (AIS) Grade.
Is injury Complete? If YES, AIS=A
NO ↓
Is injury Motor Complete? If YES, AIS=B
NO ↓ (No=voluntary anal contraction OR motor function more than three levels below the motor level on a given side, if the patient has sensory incomplete classification)
Are at least half (half or more) of the key muscles below the neurological level of injury graded 3 or better?
NO ↓ AIS=C
YES ↓ AIS=D
If sensation and motor function is normal in all segments, AIS=E
Note: AIS E is used in follow-up testing when an individual with a documented SCI has recovered normal function. If at initial testing no deficits are found, the individual is neurologically intact and the ASIA Impairment Scale does not apply.

6. Determine the zone of partial preservation (ZPP).
The ZPP is used only in injuries with absent motor (no VAC) OR sensory function (no DAP, no LT and no PP sensation) in the lowest sacral segments S4-5, and refers to those dermatomes and myotomes caudal to the sensory and motor levels that remain partially innervated. With sacral sparing of sensory function, the sensory ZPP is not applicable and therefore "NA" is recorded in the block of the worksheet. Accordingly, if VAC is present, the motor ZPP is not applicable and is noted as "NA".

APPENDIX B: COMBAT NEURO EXAM WORKSHEET

- Need Safety Pin or Needle DATE:_____ TIME:_____
- Perform all elements for all patients with a fracture of the vertebral body (excludes stable isolated transverse or spinous process fractures) noted on CT scan.

Fractured Vertebrae: (circle all that apply)

[D] >½ the muscles below level of injury have motion against gravity

[E] Normal

NEURO LEVEL: _____ (Lowest level with normal sense and at least antigravity strength)1

Incomplete Syndrome: (SCI – Occ-T11 Fx) (Conus – T12-L2 Fx) (CES – L3-Sacrum)

MF = middle finger; SF = small finger; * Suspect NORMAL strength, but limited due to pain; NT = Not Tested

APPENDIX C: SCREENING FOR BLUNT CEREBROVASCULAR INJURY

Expanded Screening Criteria for Blunt Cerebrovascular Injury (BCVI)[12]

Signs and Symptoms of BCVI

- Arterial hemorrhage from neck, nose, or mouth.
- Cervical bruit in patient <50 years of age.
- Cervical hematoma.
- Focal neurologic deficit inconsistent with head CT.
- Ischemic change on head CT.

Risk Factors for BCVI

- High-energy mechanism.
- LeFort II or III facial fracture, or mandible fracture.
- Skull or skull-base fracture.
- Severe TBI, as defined by GCS < 6.
- Cervical fracture, subluxation, or ligamentous injury.
- "Clothesline," "seat-belt," or "hanging"-type mechanism of injury.
- TBI with associated thoracic injuries.
- Thoracic vascular injuries or upper rib fractures.
- Scalp de-gloving injury.
- Blunt cardiac injuries.

APPENDIX D: SUMMARY OF PERFORMANCE OF MYELOGRAPHY

(Adapted from Omnipaquetm package insert)

BACKGROUND:

Iohexol is a non-ionic, water-soluble contrast agent with 46.36% iodine content. It is excreted renally.

Available concentrations include: 140, 180, 240, 300 and 350 milligrams of iodine per milliliter.

Omnipaque 180, 240 and 300 are indicated for intrathecal use in adults.
DO NOT ADMINISTER OMNIPAQUE 140 OR 350 INTRATHECALLY.

Contraindications: known hypersensitivity to iohexol; active local/systemic infection; co-administration of intra-thecal corticosteroids; overdose; significant intra-cranial entry; use in patient with epilepsy; grossly bloody CSF; co-administration with: phenothiazines, MAOI, TCA, CNS stimulants, antipsychotics.

Adverse occurrences: headache, meningismus, nausea, seizure, anaphylaxis. With inadvertent administration of Omnipaque not indicated for intrathecal use: death, seizure, cerebral hemorrhage, arachnoiditis, renal failure, rhabdomyolysis, hyperthermia, cerebral edema.

TECHNIQUE:

A total of 3,060 milligrams of iodine should not be exceeded in one study in an adult patient.

For total columnar myelography, instill 6-12.5 mL of Omnipaque 240, or 6-10 mL of Omnipaque 300, via standard lumbar puncture over 1-2 minutes. To allow time for complete opacification of the subarachnoid space, obtain CT roughly 15-30 minutes, but not more than 1 hour, after contrast injection.

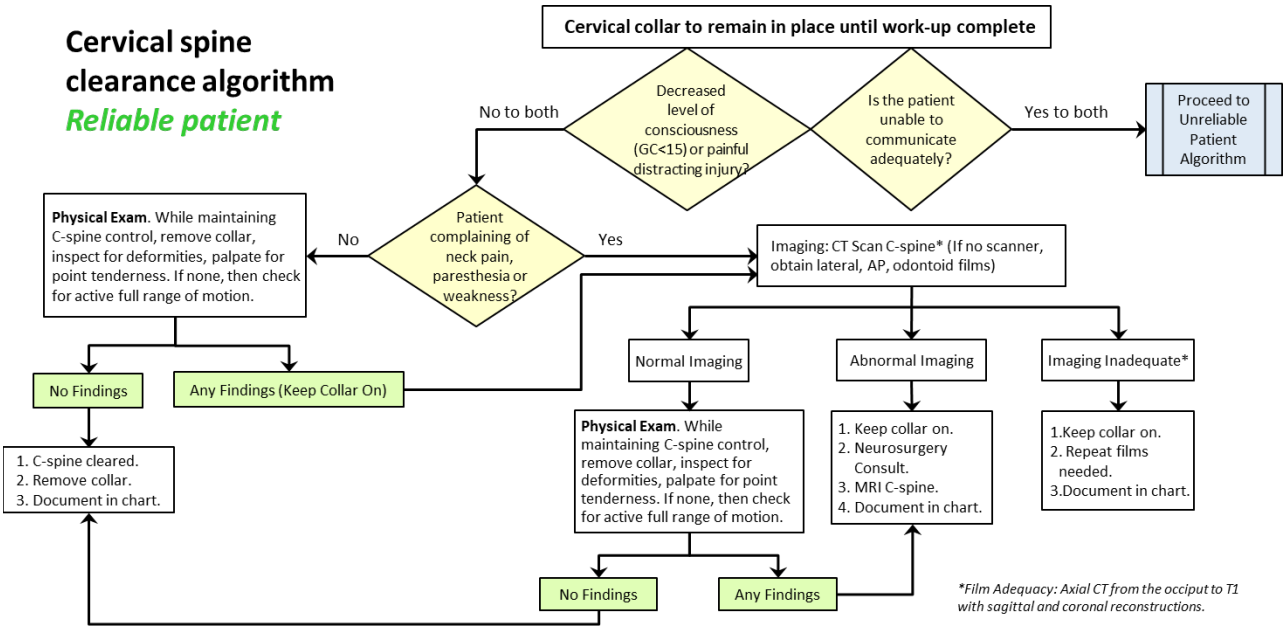
The patient should remain hydrated and observed for at least 12 hours post myelogram. Avoid excessive entry of contrast intracranially and maintain elevated head-of-bed once the study is complete.

Full details can be viewed in the OmnipaqueTM (iohexol) package insert, freely available at:

https://www.accessdata.fda.gov/drugsatfda_docs/label/2017/018956s099lbl.pdf

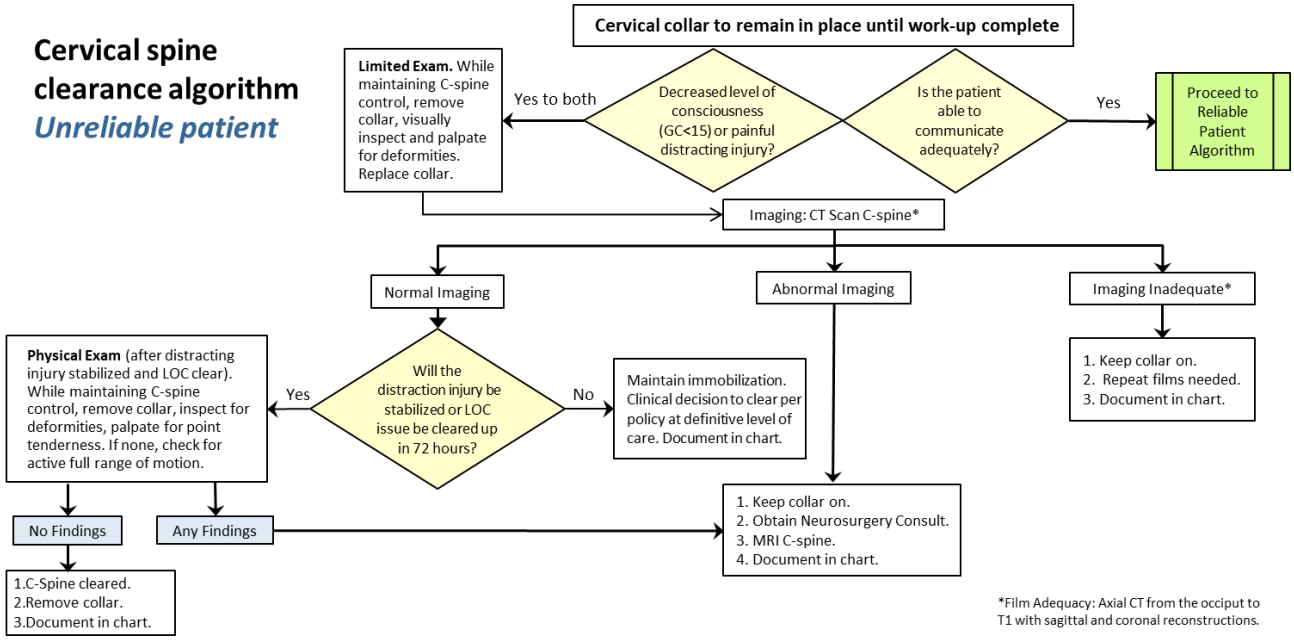
APPENDIX E: CERVICAL SPINE CLEARANCE ALGORITHM RELIABLE PATIENT

Patient is without neurologic deficit.



Cervical spine clearance algorithm
Reliable patient
Cervical collar to remain in place until work-up complete
Decreased level of consciousness (GC<15) or painful distracting injury?
Is the patient unable to communicate adequately?
No to both
Yes to both
Proceed to Unreliable Patient Algorithm
Physical Exam. While maintaining C-spine control, remove collar, inspect for deformities, palpate for point tenderness. If none, then check for active full range of motion.
No
Patient complaining of neck pain, paresthesia or weakness?
Yes
Imaging: CT Scan C-spine* (If no scanner, obtain lateral, AP, odontoid films)
No Findings
Any Findings (Keep Collar On)
1. C-spine cleared.
2. Remove collar.
3. Document in chart.
Normal Imaging
Abnormal Imaging
Imaging Inadequate*
Physical Exam. While maintaining C-spine control, remove collar, inspect for deformities, palpate for point tenderness. If none, then check for active full range of motion.
1. Keep collar on.
2. Neurosurgery Consult.
3. MRI C-spine.
4. Document in chart.
1.Keep collar on.
2. Repeat films needed.
3.Document in chart.
No Findings
Any Findings
*Film Adequacy: Axial CT from the occiput to T1 with sagittal and coronal reconstructions.

APPENDIX F: CERVICAL SPINE CLEARANCE ALGORITHM UNRELIABLE PATIENT



Cervical spine clearance algorithm
Unreliable patient
Cervical collar to remain in place until work-up complete
Limited Exam. While maintaining C-spine control, remove collar, visually inspect and palpate for deformities. Replace collar.
Yes to both
Decreased level of consciousness (GC<15) or painful distracting injury?
Is the patient able to communicate adequately?
Yes
Proceed to Reliable Patient Algorithm
Imaging: CT Scan C-spine*
Normal Imaging
Abnormal Imaging
Imaging Inadequate*
Physical Exam (after distracting injury stabilized and LOC clear). While maintaining C-spine control, remove collar, inspect for deformities, palpate for point tenderness. If none, check for active full range of motion.
Yes
Will the distraction injury be stabilized or LOC issue be cleared up in 72 hours?
No
Maintain immobilization. Clinical decision to clear per policy at definitive level of care. Document in chart.
1. Keep collar on.
2. Repeat films needed.
3. Document in chart.
No Findings
Any Findings
1. Keep collar on.
2. Obtain Neurosurgery Consult.
3. MRI C-spine.
4. Document in chart.
1.C-Spine cleared.
2.Remove collar.
3.Document in chart.
*Film Adequacy: Axial CT from the occiput to T1 with sagittal and coronal reconstructions.

APPENDIX G: CERVICAL SPINE CLEARANCE STATUS

Download form here:
https://jts.health.mil/assets/docs/forms/Cervical_Spine_Clearance_Status_Notes.pdf

Cervical Spine Clearance Status Notes
Joint Trauma System

Mechanism: ☐ Explosive ☐ M/C ☐ Fall ☐ Other

Notes:

Collar placed: ☐ Prehospital ☐ Hospital ☐ No collar

Patient reliable? ☐ Yes ☐ No Reason unreliable? ☐ Altered Mental Status (GCS<15) ☐ Significant Distracting Injury

Notes:

Patient complaints ☐ None ☐ Neck pain (specify location:) ☐ Paresthesia

Notes:

Physical Findings

Inspection: ☐ Normal ☐ Abnormal specify:

Palpation: ☐ Normal ☐ Point tenderness ☐ Deformity

Notes:

Active range of motion: ☐ Full ☐ Limited specify:

Notes:

Imaging Studies (CT is standard. Films acceptable only when CT is unavailable.)

CT scan: ☐ Normal ☐ Abnormal specify:

Notes:

Lateral: ☐ Normal ☐ Abnormal specify:

AP: ☐ Normal ☐ Abnormal specify:

Odontoid: ☐ Normal ☐ Abnormal specify:

C L E A R A N C E

Cervical spine is:

☐ CLEAR of significant injury and instability on the basis of the following:
- ☐ Normal exam in completely reliable patient with no need for imaging
- ☐ Normal imaging of full C-Spine and normal exam.

☐ NOT CLEAR on the basis of the following:
- ☐ Neurological complaint or abnormal physical exam finding
- ☐ Abnormal imaging
- ☐ Unreliable patient at time of evacuation/final disposition

Medical Record (Rev. May 2018)

APPENDIX H: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Chemical, Biological, Radiological and Nuclear (CBRN) Injury Response Part 2: Medical Management of Chemical Agent Exposure (CPG ID:69)

This guideline is intended for use in conjunction with Tactical Combat Casualty Care Guidelines as an organized approach to the care of CBRN casualties.

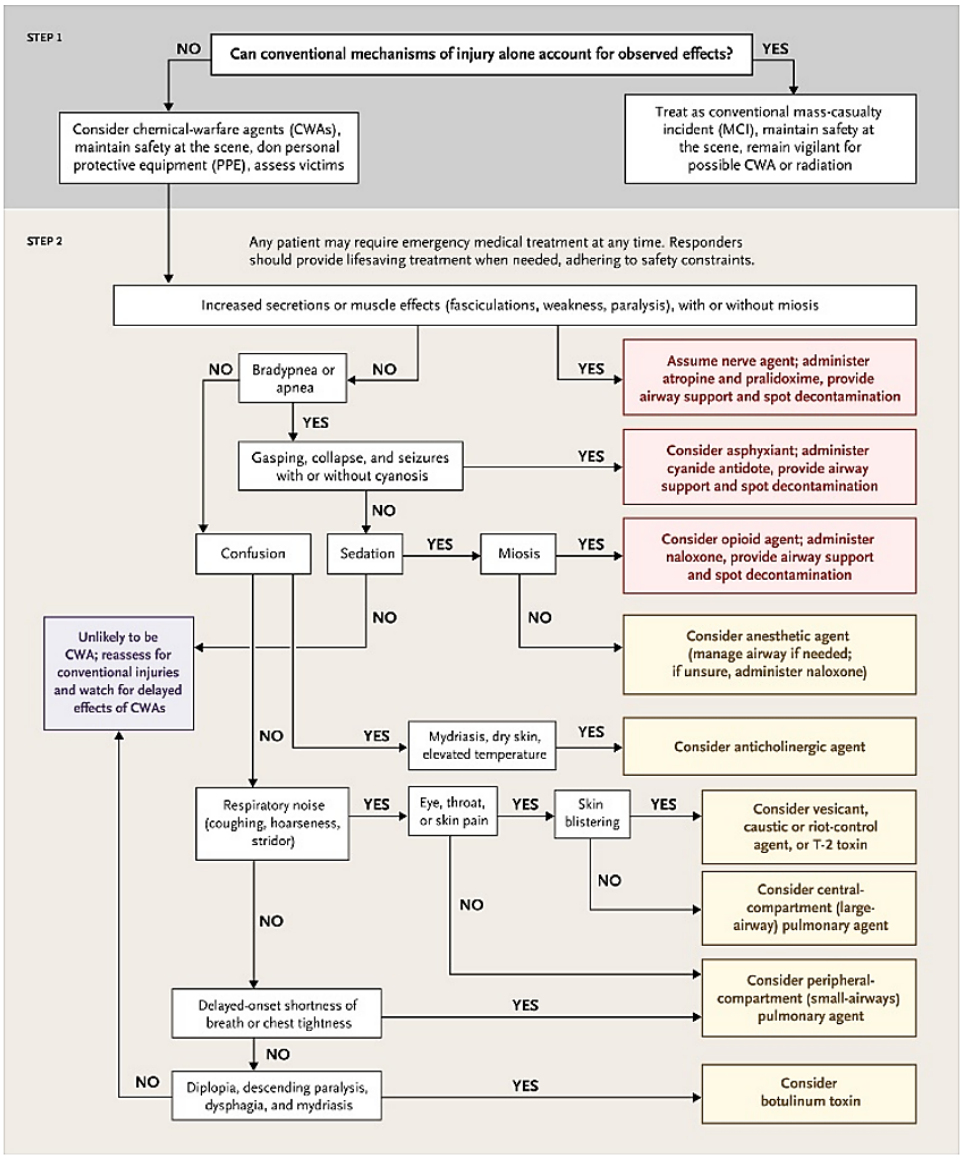
INTRODUCTION

The following is a review of the medical management of specific chemical agents in the continuum of care from point of injury (POI) through Role 3. More detailed information is available in the Field Management of Chemical and Biological Casualties Handbook.[1] Rapid reference cards are included for each category of agent. Discussion of the recommendations included in the rapid reference cards are in the text below. Additionally, the below flow chart can be referenced to rapidly triage for chemical warfare agents based on clinical presentation. Diagnostic testing and/or treatment decisions will be made based on resource availability and the tactical situation at each phase of care. Tactical combat casualty care guidelines should be incorporated into the care of the chemically exposed casualty using (MARCHE)[2] as described in the JTS Chemical, Biological, Radiological and Nuclear Injury Response Part I: Initial Response Clinical Practice Guideline. [2]

Figure 1. Toxidrome-based Rapid Identification of Chemical-Warfare Agent Classes



STEP 1
Can conventional mechanisms of injury alone account for observed effects?
NO
YES
Consider chemical-warfare agents (CWAs), maintain safety at the scene, don personal protective equipment (PPE), assess victims
Treat as conventional mass-casualty incident (MCI), maintain safety at the scene, remain vigilant for possible CWA or radiation
STEP 2
Any patient may require emergency medical treatment at any time. Responders should provide lifesaving treatment when needed, adhering to safety constraints.
Increased secretions or muscle effects (fasciculations, weakness, paralysis), with or without miosis
Bradypnea or apnea
Assume nerve agent; administer atropine and pralidoxime, provide airway support and spot decontamination
Gasping, collapse, and seizures with or without cyanosis
Consider asphyxiant; administer cyanide antidote, provide airway support and spot decontamination
Confusion
Sedation
Miosis
Consider opioid agent; administer naloxone, provide airway support and spot decontamination
Unlikely to be CWA; reassess for conventional injuries and watch for delayed effects of CWAs
Consider anesthetic agent (manage airway if needed; if unsure, administer naloxone)
Mydriasis, dry skin, elevated temperature
Consider anticholinergic agent
Respiratory noise (coughing, hoarseness, stridor)
Eye, throat, or skin pain
Skin blistering
Consider vesicant, caustic or riot-control agent, or T-2 toxin
Consider central-compartment (large-airway) pulmonary agent
Consider peripheral-compartment (small-airways) pulmonary agent
Delayed-onset shortness of breath or chest tightness
Diplopia, descending paralysis, dysphagia, and mydriasis
Consider botulinum toxin

CYANIDE EXPOSURE

BACKGROUND

Cyanide has historically been an uncommon warfare agent; however, its lethality and availability worldwide make it a realistic and potential agent of terrorism. Cyanide was found in the Tokyo subway after the Sarin attacks[3,4] and reported to have possibly been a contaminant in the explosives of the World Trade Center bombing in 1993.[5,6] Cyanide is most likely to be employed in the volatile, water soluble, and liquid forms of hydrogen cyanide (AC) and cyanogen chloride (CK). The reactive salt forms of cyanide (potassium, sodium, and calcium cyanide) are also used in industry and produce hydrogen cyanide (HCN) gas when mixed with an acid. Cyanide is highly volatile and readily transforms from liquid to the potent gas form (HCN). HCN is released by pyrolysis of synthetic polymers such as burning plastics and may be released in structural fires. Because it is lighter than air, it disperses quickly in open spaces. Cyanogen chloride, however, is heavier than air and thus is a more persistent agent.

SIGNS AND SYMPTOMS

Cyanide can cause symptoms within seconds to minutes of inhalational exposure. While it is classified as a blood agent, the early symptoms are cardiotoxicity and central nervous system (CNS) effects. The initial symptoms can be non-specific and transient. Dizziness, headache, weakness, diaphoresis, and dyspnea are all possible and leave a broad differential diagnosis. The well-described odor of bitter almonds is not a reliable sign as many cannot detect the odor. The hallmark clinical presentation that leads to diagnosis is tissue hypoxia without cyanosis (pulse oximetry may be normal) with the finding of metabolic acidosis. Without rapid treatment, the patient is likely to rapidly progress to coma, hemodynamic compromise, arrhythmias, seizures, secondary cardiac arrest, and eventually death.

DECONTAMINATION

Victims exposed to cyanide should be rapidly removed from the location of exposure while ensuring that the rescuer is protected. For gas exposure, evacuating from the location and then removing all clothing addresses the majority of decontamination. Further decontamination with irrigation solutions can be done, but treatment with antidote is the first priority and should not be delayed.

DIAGNOSTICS

Prompt diagnosis to facilitate treatment is essential. However, in a tactical environment, the availability of diagnostic adjuncts is limited. Cyanide levels are not rapidly available and not useful in the acute phase of care. The clinical picture coupled with arterial blood gas demonstrating metabolic acidosis and very high lactate levels should alert the clinician to possible cyanide exposure.[7] This can be an extremely challenging diagnosis in the setting of trauma with massive hemorrhage and hypovolemic shock. Thus a high index of suspicion and awareness of intelligence indicating risk of exposure are key to early diagnosis. Drawing an arterial and venous blood gas at the same time and comparing the oxygen content can be helpful. “Arterialization of venous blood” (similar color/PaO2 of samples) can help round out the clinical picture. From a practical standpoint, it is unlikely that the provider will have diagnostic support in the hot or warm zone, so the decision to treat will be entirely clinical. Fortunately, with the availability of hydroxocobalamin (discussed in detail below), the side effects of empiric administration of the antidote are minimized when compared to the previously used cyanide antidote kit.

Table 1. Blood Agents

Blood Agents - Cyanide Treatment	**Agent Properties** Hydrogen cyanide, Cyanogen chloride Volatile water-soluble liquid M8 Paper: does not detect Odor: Bitter almonds	**PPE Requirements** Mask and AP-PPE, JLIST, or UIPE **Lethality** LCt50 HCN 500mg min/m3 LCt50 CK 1.1g min/m3	**CRESS Symptomatic Presentation** **C**: altered or unconscious **R**: normal to apneic **E**: normal unless vapor irritant **S**: none **S**: may be flushed (50% of the time)
POI Hot Zone	Immediate Action: Self Aid, Buddy Aid, Move (Upwind, Upstream, Uphill) Away from Threat **M^2:** **M**assive hemorrhage / **M**ask check **A^2:** **A**irway (assess) / **A**ntidote (Cyanokit) **R^2:** **R**espiration (assess) / **R**apid Spot Decon **E:** **E**xtraction (egress away from threat)		High concentrations of cyanide can result in death within seconds to minutes. Early symptoms may include dizziness, headache, weakness, diaphoresis, and dyspnea/hyperpnea. CNS and cardiotoxicity occur due to intracellular hypoxia. Consider amyl nitrite (0.3mL ampule)
Dirty CCP Warm Zone	**M^2 A^2 R^2** Reassessment, clear airway, O2 as needed, maintain filtered air **Decon & Cutout:** Remove and bag equipment, PPE, and clothing Evacuation from exposure + clothing removal is adequate decon Can further decontaminate skin with irritation solution, but priority is antidote **C^2:** **C**irculation (assess vitals, resuscitate) / Countermeasures (Cyanokit) **H^2:** **H**ypothermia (prevent) / Head wounds (assess mental status--altered due to agent or TBI?) **E:** **E**vacuation		**Cyanokit 5gm IV over 5 min in 200mL NS** Decision to give in hot or warm zone is based on clinical presentation. Unlikely to have diagnostic adjuncts (lactate, arterial/venous samples) prior to cold zone. If Cyanokit (hydroxocobalamin) antidote is not available, aggressive supportive care may be sufficient treatment.
Cold Zone	**(MARCHE)^2 Reassessment** **C^2**: Circulation (Assess vitals, resuscitate)/Countermeasures **Supplemental O_2** (even with normal SpO_2) **Cyanokit** 5gm IV over 5 min in 200mL NS (May give second dose if first not effective) **H^2**: Hypothermia (HPMK, fluid warmer)/Head wounds (treat elevated ICP, Neuro exam, MACE)	**PFC**: Supportive care Anticipate hemodynamic compromise, seizures, cardiac arrhythmias **Bedside diagnosis**: draw venous and arterial samples, similar color of samples indicates arteriolization of venous blood **Lactate** elevated, cyanide levels not useful *When Cyanokit (hydroxocobalamin) antidote is not available, cyanide antidote kit may be used; side effect methemoglobinemia and vasodilation are problematic if concomitant trauma*

TREATMENT

The mainstay of treatment is antidote therapy with hydroxocobalamin. Attention to supportive care is a critical part of the resuscitation. Airway management, intravenous access, and cardiac monitoring can support a cyanide-poisoned patient. Supplemental oxygen is beneficial and may enhance antidote efficacy and promote cyanide respiratory excretion along with other metabolic processes. Historically, cyanide was treated with the cyanide antidote kit consisting of amyl nitrite, sodium nitrite, and sodium thiosulfate. The nitrites induce methemoglobinemia, as a side effect which may be detrimental in a patient with concomitant trauma. The preferred antidote is now hydroxocobalamin (Cyanokit). However, if hydroxocobalamin is not available, the cyanide antidote kit can be used. An inhaled ampule of amyl nitrite can be a temporizing measure until IV/IO access is established.

Hydroxocobalamin (vitamin B12a) acts as a chelating agent and binds with cyanide to form cyanocobalamin (vitamin B12). The dose of hydroxocobalamin for cyanide toxicity is much higher than the dose used for other therapeutic indications, therefore the commercially prepared hydroxocobalamin is needed to get the optimal dose without volume overload: 5gm IV (70mg/kg in pediatric patients) over 15 minutes. The dose can be repeated for severe toxicity or inadequate response to the initial dose. It is as effective as epinephrine in the setting of cardiac arrest from cyanide. It may cause a red discoloration of the skin and urine that persists for several weeks. Other side effects are mild. The decision to administer hydroxocobalamin within the hot or warm zone has to be weighed against the tactical risk of stopping to gain IV or IO access and establishing the infusion.

Other treatment regimens as well as prophylactic measures have been explored in the literature and are summarized in the table below.

Table 2. Other Treatment Regimens

Agent	Intervention	Highlights	References
Cyanide Treatment	hydroxocobalamin (Cyanokit®) 5gm IV over 15 min (may repeat dose for severe toxicity or poor clinical response). Can be given IO	Effective as single agent. As effective as epinephrine in the setting of cardiac arrest	Sauer 2001[8] Bebarta 2010[9] Bebarta 2012[10] Bebarta 2014[11] Brouard, 1987[12]
	Cyanide antidote kit Amyl nitrite 0.3mL Sodium nitrite 300mg Sodium thiosulfate 12.5gm	Suboptimal due to formation of methemoglobinemia which could be deleterious in the setting of concomitant trauma. Thiosulfate alone not effective	Bebarta 2012[10] Hall 1987[13]
	hydroxocobalamin + sodium thiosulfate	Theoretical benefit, but did not result in benefit in swine model of shock from cyanide poisoning	Bebarta 2012[10]
	Cobinamide	As effective as hydroxocobalamin in animal model. May have future promise for IM/IO use	Bebarta 2014[14]
Cyanide Prophylaxis	Alpha-ketoglutarate	Potential benefit as prophylactic and/or adjunct agent with antidote	Dulaney 1991[15]
	N-acetylcysteine (NAC)	Benefit up to 60 minutes before exposure when given with alpha-ketoglutarate	Dulaney 1991[15]
	Dihydroxyacetone (DHA)	Benefit in animals (oral and IV)	Niknahad 2002[16]
Hydrogen Sulfide (acts as simple asphyxiant/ irritant but included as blood agent due to HS cytochrome oxidase inhibition)	Sodium nitrite 300mg IV over 5-7 minutes	Anecdotal evidence if given shortly after exposure. Supportive care is often sufficient treatment if patient survives exposure	Hoffman 2015[17]

NERVE AGENT EXPOSURE

BACKGROUND

Nerve agents, or acetylcholinesterase inhibitors, are some of the most lethal substances ever to be weaponized. These agents exist in multiple forms from thick viscous liquids to highly dissolvable gases. They are chemically similar to organophosphates used for pesticides, and the syndromes they cause are much more common in farming communities than they are on the battlefield. The most lethal forms only require 1/1000th of an ounce to obtain a lethal dose in 50% of exposed population (LD50).

Nerve agents consist of mainly two classes, V agents and G agents. V agents are viscous in nature and can be spread in numerous ways. They are extremely dangerous if touched or ingested but can also pose a vapor hazard in close proximity. G agents are liquids at room temperature and are extremely effective as chemical weapons due to the ability to quickly expose a large number of people to lethal inhaled doses by vapor exposure.

Physiologically, these agents bind to acetylcholinesterase, thus inhibiting breakdown of acetylcholine. The two main types of cholinergic receptors where nerve agents interact are muscarinic and nicotinic. Muscarinic receptors are located in the smooth muscles and the glands. Symptoms caused by over-stimulation of muscarinic receptors can be recalled using the DUMBBELS mnemonic (Diarrhea, Urination, Miosis, Bronchorrhea/Bronchoconstriction, Bradycardia, Emesis, Lacrimation, Salivation). These symptoms can be countered by atropine (discussed later in the treatment section). Nicotinic receptors located in skeletal muscle and nerve ganglia are also affected by nerve agents. Symptoms caused by over-stimulation of nicotinic receptors can be remembered by using the first letter of the days of the week as a memory assist (Mydriasis, Tachycardia, Weakness, Hypertension, Fasciculations). Administration of pralidoxime (2PAM) restores cholinesterase activity which typically results in improvement of the nicotinic symptoms.

SIGNS AND SYMPTOMS

Nerve agent poisoning can range from mild to severe; a severe exposure may quickly lead to death if not reversed. Rapid antidote treatment is extremely important since some nerve agents can irreversibly bind to acetylcholinesterase (for example, the half-life for irreversible binding, termed aging half-life, for soman/GD is two minutes).

For mildly affected individuals not wearing eye protection, miosis is commonly seen. Other obvious muscarinic effects include severe lacrimation and profuse sweating, followed by nausea and vomiting, along with dyspnea and shortness of breath due to bronchorrhea and bronchoconstriction. More severely affected patients will have all of these signs and symptoms as well as profound weakness, fasciculations, seizures, loss of consciousness, apnea and death.

The speed of symptom onset depends on the route of exposure and dose of the agent. Inhalational exposure tends to result in faster onset of symptoms and can quickly cause death due to rapid systemic distribution. Dermal exposures, such as exposures with V agents, can cause delayed onset of symptoms.

Table 3. Nerve Agents

Nerve Agent (GA, GB, GD, GF, VX) and Organophosphate Treatment	**Agent Properties** Vapor or liquid. Variable aging (**GD** 2min) G non-persistent, V persistent M8 Paper: G - yellow, V- green	**PPE Requirements** Mask and AP-PPE, JLIST, or UIPE **LETHALITY (VX most potent)** LCt50 15-70mg min/m3 LD50 3-4000mg	**CRESS Symptomatic Presentation** **C**: altered, unconscious, seizures **R**: tachypnea, wheezing, respiratory distress **E**: miosis (may not be present with some organophosphates) **S**: copious secretions (salivation, lacrimation, bronchorrhea) **S**: diaphoresis
POI HOT ZONE	**Immediate Action:** Self Aid**,** Buddy Aid, Move (Upwind, Upstream, Uphill) Away from Threat **M²**: **M**assive hemorrhage / **M**ask check **A²**: **A**irway (assess) / **A**ntidote (ATNAAx3, CANAx1) **R²**: **R**espiration (assess) **/ R**apid Spot Decon (RSDL, M295, Fibertect) **E**: **E**xtraction (egress away from threat)		Exposure to vapor causes almost immediate symptoms while liquid exposure may have minutes to hours delay in symptoms Muscarinic symptoms (**D**iarrhea, **U**rination, **M**iosis, **B**ronchorrhea, **B**radycardia, **E**mesis, **L**acrimation, **S**alivation) Nicotinic symptoms: (**M**ydriasis, **T**achycardia, **W**eakness, **H**ypertension, **F**asciculations) and seizures
Dirty CCP WARM ZONE	**M² A² R²** Reassessment, clear airway, O_2 as needed, maintain filtered air **Decon & Cutout:** ▪ Remove and bag equipment, PPE, and clothing ▪ Wipe away gross contamination, RSDL cut line, Cut out ▪ RSDL residual contamination on skin (>2min contact time, then wipe away) ▪ Remove and replace contaminated treatments (tourniquets, chest seals, etc) **C²: C**irculation (assess vitals, resuscitate) / **C**ountermeasures (atropine, pralidoxime, benzodiazepines) **H²: H**ypothermia (prevent) / **H**ead wounds (assess mental status--altered due to agent, antidote, or TBI?) **E**: **E**vacuation		Atropine given mistakenly to an individual not exposed to nerve agent may cause tachycardia, dry mouth, and anhydrosis and predispose to heat injury. When uncertain, favor treatment.
COLD ZONE	**(MARCHE)² Reassessment** **C2: C**irculation (Assess vitals, resuscitate) **/ C**ountermeasures Use the following as symptoms dictate: ▪ Atropine 20mg in 250mL NS IV/IO, titrate to dry respiratory secretions ▪ Pralidoxime (1-2gm in 250mL NS) IV/IO over 15-30min ▪ Benzodiazepines (midazolam preferred) 2mg IV/IO/IM, titrate to effect ▪ Scopolamine 0.8mg IV/IM after ATNAA x3 (as an adjunct to atropine) **H²: H**ypothermia (HPMK, fluid warmer) / **H**ead wounds (treat elevated ICP, Neuro exam, MACE)		**PFC**: Supportive care: Reassess frequently, follow protocols for respiratory or cardiac compromise. Patients with ONLY miosis or mild rhinorrhea do not require treatment. Acetylcholinesterase levels NOT diagnostic but may be trended. Chest X-ray useful to monitor for pulmonary edema and secondary pneumonia. Benzodiazepines can help control muscle fasciculations and seizures.

DECONTAMINATION

As with most chemicals, removing the exposed patient from the contaminated area to prevent further exposure and damage is the most important step. In vapor exposures, this means removing the casualty from the area and quickly removing any article of clothing or piece of equipment with possible agent contamination.

Reactive skin decontamination lotion (RSDL) is largely accepted as the most effective decontaminate for nerve agent dermal exposure. Covering all exposed skin with RSDL as quickly as possible can be a life-saving measure. If RSDL is not available, 0.5% hypochlorite solution or soap and water are alternatives. Decontamination should not be delayed if RSDL is not available. For casualties exhibiting moderate to severe symptoms (respiratory distress, seizures, altered consciousness), antidotes should be administered immediately while initiating decontamination.

NERVE AGENT DIAGNOSTICS

Diagnosis of nerve agent exposure is based on rapid identification of the clinical symptoms and identification of the agent through detection methods. Laboratory measurement of serum acetylcholinesterase levels is not useful for nerve agent exposure since the value does not correlate with signs and symptoms or prognosis. There is no utility in baseline ACHE levels due to intra-individual variability.

NERVE AGENT TREATMENT

Nerve agent antidotes include 2PAM, atropine, and benzodiazepines. Autoinjectors to treat nerve agent toxicity are available as Autoinjector Nerve Agent Antidote (ATNAA) which contains atropine and 2PAM, and Convulsant Antidote Nerve Agent (CANA) which contains the benzodiazepine diazepam.

2PAM

Pralidoxime (ATNAA autoinjector or IV/IO) reverses the bond between the acetylcholinesterase and the nerve agent and thus prevents irreversible binding to acetylcholinesterase, termed aging. 2PAM is available both in autoinjector form as well as in an IV form. 2PAM is known to work synergistically with atropine (some 30x greater). The are other oximes with varying effects depending on the agent, but pralidoxime is the available agent in DoD inventory.

Atropine

Atropine (ATNAA autoinjector or IV/IO) is used to treat the muscarinic effects. Atropine will help dry secretions (bronchorrhea) and counter the effects of the bronchoconstriction caused by the nerve agent. The amount of nerve agent and the degree of symptoms a patient is experiencing will determine the amount of atropine required to control symptoms. Large doses of atropine may be required to counter the effects of some nerve agent exposures, in particular organophosphates. Tachycardia is NOT a contraindication for atropine administration, as tachycardia may be secondary to respiratory distress. Therefore, atropine treatment should be titrated to achieve reversal of life-threatening bronchorrhea and bronchoconstriction even in the setting of tachycardia.

Benzodiazepines

Benzodiazepines, such as diazepam (CANA) or midazolam are the mainstay of seizure treatment. Benzodiazepines may also help counter nicotinic effects, particularly muscle fasciculations. Current literature recognizes midazolam as the most effective seizure reversal agent, based on animal studies. Midazolam has the fastest bioavailability when given intramuscularly (IM). Diazepam is the benzodiazepine in autoinjectors and is efficacious, but it is entirely appropriate to use another benzodiazepine when IV access has been established or when autoinjectors have been depleted.

Nerve agent antidotes may be dosed based on the severity of symptoms. However, in a field environment when the amount and type of nerve agent exposure are unknown, give 3 ATNAAs and 1 CANA for any symptomatic patient (other than isolated miosis) with suspected nerve agent exposure. If symptoms persist beyond this treatment, consider an atropine drip (see atropine/scopolamine protocol in Appendix A). For severe poisoning, additional 2PAM can be given after delivering 3 ATNAAs. There is a paucity of literature to guide dosing but current subject matter expert consensus is to dose an additional 500mg IV/IO over 5 minutes and then an infusion of 10mg/kg/hr until clinical improvement is stable which may require infusion for more than 24 hours. (See Appendix B.)

Prophylaxis

The planning considerations and the risk:benefit analysis in the decision to use pyridostigmine bromide (PB) prophylaxis is outside the scope of this CPG. However, it is important for providers to understand the clinical effects experienced by those on pyridostigmine prophylaxis and how pre-treatment can affect clinical presentation and response to treatment. Pyridostigmine (30mg tablet) is approved by the FDA for use as a pretreatment to exposure to soman, based on efficacy in reducing soman lethality when used in conjunction with 2PAM and atropine treatment in animals. (See FDA Pyridostigmine Bromide Package Insert.)[18] There are no human studies.

Pyridostigmine acts by inhibiting a portion (20-40%) of peripheral acetylcholinesterase. It does not readily cross the blood brain barrier so it does not cause central inhibition. Thus side effects of pyridostigmine prophylaxis are typically mild cholinergic or nicotinic symptoms (diarrhea, abdominal pain, and dysmenorrhea were the most common side effects in volunteers). Pyridostigmine and mefloquine (for malaria prophylaxis) taken together may have an additive effect on the gastrointestinal tract with increased diarrhea. Opioid-associated bradycardia may be worsened when pyridostigmine is combined with opioids. Pyridostigmine may enhance the activity of depolarizing neuromuscular blocking agents (succinylcholine) but may require a higher dose of non-depolarizing neuromuscular blockers. Treatment for nerve agent toxicity is the same for patients on pyridostigmine prophylaxis

Table 4. Nerve Agent Treatment/Intervention

Agent	Intervention	Summary of evidence	References
Nerve agents **GA** **GB** **GD** **GF** **VX**	**Atropine** 2.1 mg in each ATNAA autoinjector and 2 mg in each separate atropine autoinjector; initial dose 6.1 mg (3 ATNAAs); then titrate in 2-mg increments (anticipate 10-20 mg in the first several hours)	Atropine well established as anticholinergic. Helps control seizure activity.	McDonough 2001[19] Sidell 1997[20] Sidell 1974[21] Shih 1999[22] Taylor 1985[23] Ward 1962[24]
	Scopolamine* Dosing not well established	Penetrates the blood-brain barrier and controls CNS effects of nerve agents; enhanced survival in animals when used as adjunct with 2-PAM Cl and atropine; a dose of up to 1 mg may result in a marked decrease in total atropine required	Harris 1994[25] Koplovitz 2010[26] McDonough 2001[19]
	Pralidoxime chloride (2-PAM Cl)^ 600mg by autoinjector (3x) 1-2 gm IV/IO over 20-30 minutes	Most studied and only oxime in U.S. inventory. 2-PAM effectiveness is agent dependent. In guinea pigs, 2-PAM Cl is effective against sarin and VX.	Clement 1989[27] Dawson 1994[28] Gunnarson 2000[29] Kassa 2002[30] Snider 2016[31] Wilhelm 2014[32]
	Obidoxime^**	Obidoxime offered protection against tabun, sarin, VX, and pesticide oxons in guinea pigs.	Dawson 1994[28] Kassa 2002[30] Wilhelm 2014[32] Worek 2007[33]

Agent	Intervention	Summary of evidence	References
	HI-6^**	HI-6 is considered a more broad-spectrum oxime and offered protection against tabun, sarin, cyclosarin, VX, and paraoxon in guinea pigs.	Dawson 1994[28] Hamilton 1989[34] Kassa 2002[30] Wilhelm 2014[32]
	Benzodiazepines*** Diazepam - autoinjector Standard IV/IO dose for seizures 10-20 mg (up to 40 mg may be needed) Midazolam - off label dosing recommendations for status epilepticus is 10 mg IM, typical IV/IO doses for seizure control start at 1-2 mg and titrate	Two cases in Tokyo sarin attack. One patient received diazepam 35 mg (for seizures) and the other 30 mg (for fasciculations) along with atropine and 2PAM. Both recovered without sequelae. Some data to suggest that benzodiazepines can be useful for anxiety and restlessness that may precede seizures. Midazolam shown to be effective at a lower dose and to be more rapidly absorbed IM than diazepam in animal models	Marrs 2007[35] McDonough 2001[19] Shih 2002[36]

*While scopolamine is an FDA-approved drug, its use for nerve-agent poisoning is off-label
**Obidoxime and HI-6 are not FDA approved or available in the U.S.
***While benzodiazepines are routinely used for termination of seizures, this is an off-label use of this class of medications.
^ Efficacy of oximes is species dependent, so it is difficult to extrapolate effectiveness in humans from existing animal studies.

PULMONARY AGENT EXPOSURE

BACKGROUND

Pulmonary agents (also referred to as toxic industrial chemicals and choking agents) hold historical significance as the forerunners of modern chemical warfare and still hold relevance today as likely chemical culprits given their availability. Chlorine and phosgene are produced and stored in large quantities worldwide, and could have devastating effects when vaporized. There are other agents which can produce chemical lung injury such as ammonia, hydrogen sulfide, zinc oxide, phosphorus smokes, and perfluoroisobutylene (by-product of Teflon). These agents are irritating to the lungs, but are less likely to be used in a chemical attack.

Chlorine becomes a gas at -34 ° C, and is therefore stored as a compressed liquid. Phosgene becomes a toxic gas at 47 °F. The extent of injury caused by either gas is a function of the duration and concentration of exposure. Other variables that impact toxicity include respiratory rate and depth (minute ventilation) and possibly body position.

Exposures to 30ppm of chlorine will cause coughing; more serious damage to the lungs occurs at levels above 40 to 60ppm for more than 30 minutes. Phosgene is more surreptitious and toxicity may occur below its odor threshold of 0.4ppm with prolonged exposure. Additionally olfactory fatigue can occur so an individual may only transiently notice the warning odor. Phosgene IDHL (Immediately Dangerous to Life or Health) is 2ppm whereas chlorine IDHL is 100ppm.

Both gases react with moisture in the respiratory system and undergo hydrolysis. Chlorine causes lung damage through reactions to form hydrochloric and hypochlorous acids, which in turn react with sulfhydryl groups of cysteine and cause enzyme inhibition. In addition to this reaction, hydrolysis of chlorine results in free radical generation that can lead to direct cell injury and death. Phosgene also reacts with water to form carbon dioxide

and hydrogen chloride. However, the major toxicity of phosgene is believed to occur through acylation in which phosgene interacts with sulfhydryl, amine, and hydroxyl groups causing protein and lipid denaturation, disruption of membrane structure and interference with enzyme function. Phosgene also disrupts the pulmonary surfactant layer.

PULMONARY AGENT SIGNS AND SYMPTOMS

Both gases have the ability to cause asphyxia due to displacement of oxygen if released in a confined space. More commonly, the gases act as irritants and cause damage to the respiratory tract through the mechanisms described above. Lastly, the gases can cause a systemic inflammatory response.

Chlorine has an unpleasant odor and is highly irritating. Because chlorine undergoes more rapid hydrolysis when contacting mucous membranes, it causes more immediate symptoms in the moist areas of the eyes, mouth, and upper airways. Eye pain, blepharospasm, and lacrimation are common. Other symptoms may include headache, salivation, dyspnea, cough, hemoptysis, chest burning, and vomiting.

Physical examination may reveal tachycardia, tachypnea, and possibly cyanosis. If eye irritation is present, evaluation for corneal burns/abrasions should be done with fluorescein staining of the eye. In the presence of oropharyngeal erythema, there may be more significant distal injury requiring careful assessment of the airway. Stridor, hoarseness, or aphonia may indicate laryngeal edema or laryngospasm. Oropharyngeal secretions may be copious.

Phosgene smells of fresh mown hay. It has more insidious effects, and early symptoms may be mild or absent. Typical onset of phosgene-induced symptoms occurs 2 to 6 hours after exposure and delayed symptoms have been described up to 15 hours post exposure. The major effects of phosgene are on peripheral airways, therefore dyspnea, chest tightness or pain, and cough are common symptoms. Development of hypoxia and pulmonary edema may occur hours after the onset of symptoms. Fluid shifts secondary to pulmonary edema may result in hypovolemia. Early onset of pulmonary edema portends a grave prognosis.

PULMONARY AGENT DECONTAMINATION

Safe removal from the toxic gas is the priority in chlorine or phosgene exposure. Respiratory protection for rescuers and providers in a potential exposure area is critical. Once the casualty is removed from the exposure area, decontamination should be continued with removal of all clothing. For toxic gas exposure, this removes the majority of risk from the gases. Soap and water is adequate to complete decontamination.

PULMONARY AGENT DIAGNOSTICS

There are no readily available diagnostic tests to confirm or quantify pulmonary agent toxicity. Standard tests such as arterial blood gases and chest x-rays (CXR) should be used to guide supportive care as needed. Arterial blood gases can be useful when needed to follow oxygenation, but may be normal in the early phases of phosgene exposure. PCO2 may be elevated in patients with obstructive pathophysiology and indicate a need for bronchodilators or corticosteroids.

Much like ABGs, CXR performed shortly after exposure may be normal but the patient may progress to frank pulmonary edema within a few hours. Fortunately the CXR can reveal pulmonary edema before clinical exam findings. A baseline CXR may be useful for comparison when trying to detect subtle early findings of pulmonary edema. If the CXR is normal at 8 hours, it is unlikely the patient will develop pulmonary edema.[37]

Table 5. Pulmonary Agents

Dirty CCP WARM ZONE	**M² A² R²** Reassessment, clear airway (copious secretions), possible laryngospasm, advanced airway--be prepared for cric, ventilatory support if needed, O_2 as needed, maintain filtered air **Decon & Cutout:** ▪ Remove and bag equipment, PPE, and clothing ▪ Soap and water sufficient for skin decon ▪ Remove and replace contaminated treatments (tourniquets, chest seals, etc) **C²: C**irculation (assess vitals, resuscitate) / **C**ountermeasures **H²: H**ypothermia (prevent) / **H**ead wounds (assess mental status--altered due to agent or TBI?) **E**: **E**vacuation		Laryngospasm may occur. Anticipate airway edema and manage airway early. If advanced airway required, place largest endotracheal tube possible to facilitate suctioning. If life threatening reactive airway symptoms or dysrhythmias, consider B-agonists and/or ACLS intervention in warm zone. Weigh against delays in decon and transition to cold zone care.
COLD ZONE	**(MARCHE)² Reassessment** **C²: C**irculation (Assess vitals, resuscitate) / **C**ountermeasures ▪ Supplemental O2 ▪ Inhaled Beta agonist if wheezing (e.g. albuterol MDI) ▪ Monitor for dysrhythmia (usually transient), ACLS if indicated **H²: H**ypothermia (HPMK, fluid warmer) / **H**ead wounds (treat elevated ICP, Neuro exam, MACE)		**PFC**: Albuterol 2.5mg in 3ml NS for wheezing/bronchospasm Inhaled or systemic corticosteroids (**Inhalation Injury Protocol**) Eyes: Irrigate, evaluate for corneal burn/abrasion **Imaging:** If chest X-ray negative at 8 hrs, unlikely to develop severe pulmonary edema (delayed onset pulmonary edema may occur as late as 24 hrs with phosgene) **Severe symptoms:** PEEP, ARDS ventilation strategies, aggressive pulmonary toilet. Diuresis NOT indicated, prophylactic antibiotics NOT indicated.
Reachback: USAMRICD (410) 436-2230 DSN: 584-2230			

PULMONARY AGENT TREATMENT

Chlorine exposures may lead to copious secretions and laryngospasm shortly following exposure, therefore providers should be prepared for airway management and possibly emergent surgical airway control. It is important to remember that phosgene-exposed patients, despite being asymptomatic, need to be treated as casualties. Such casualties should be kept at rest, as exertion is associated with pulmonary edema and worse outcomes in phosgene-exposed patients. If an advanced airway is placed, a large-bore endotracheal tube will facilitate pulmonary toilet as toxic gas exposures can cause sloughing of mucosa and clogging of the airway with debris.

Intravenous fluids may be necessary in the setting of volume depletion, but should not be given empirically. Fluid overload can contribute to pulmonary edema and should be avoided. Laryngoscopy and/or bronchoscopy may be necessary, and preparations for advanced airway management must be in place should airway compromise occur. Portable ventilators with simplified automated setting (e.g. SAVe ventilators) may not be adequate for ventilation management in these patients. Because of the associated pulmonary edema, bronchospasm, and risk of ARDS, the ability to manipulate ventilator settings is crucial. Additionally, suction is a key component of maintaining patent airways, bulb suction is unlikely to be adequate and mechanical suction with the ability to do inline suction is preferred.

Advanced interventions and the supporting evidence is described in the table below. Much of the available evidence is based upon animal studies and human data is limited.

Table 6. Pulmonary Agent Intervention

Agent	Intervention	Highlights	References
Chlorine	Beta agonists (albuterol MDI) (typical bronchodilator doses)	May be useful in the setting of bronchospasm and obstructive airway disease	Nelson 2015 [38]
	Corticosteroids (typical doses given for reactive airway disease) Inhaled: fluticasone 200mcg BID budesonide 0.5-2.0mg BID	Possible benefit shown in animal studies using inhaled steroids, even without reactive airways (no human data)	Gunnarson 2000[29] Wang 2004 [39]
	Nebulized sodium bicarbonate (dilute 8.4% 1:1 with sterile water to make 4.2%)	Theoretical benefit, studies limited.	Bosse 1994 [40] Vinsel 1990 [41]
Phosgene	Corticosteroids (typical doses for reactive airway disease, IV or inhaled)	Possible benefit shown in animal studies, even without reactive airways (no human data)	Guo 1990[42] Frosolono1978[43]
	Medications that increase cAMP (aminophylline, dibutyryl adenosine 3,5 cyclic monophosphate [DbcAMP], Beta adrenergic agents)	Theoretical benefit when given early after exposure (no human data)	Sciuto 1997[44] Kennedy 1989[45]
	Ibuprofen	Reduction of pulmonary edema in rats (with pre and post exposure treatment)	Sciuto 1996[46]
	N-acetylcysteine	Reduction of pulmonary edema, lipid peroxidation, and leukotriene production in rabbits	Sciuto 1995[47]

VESICANT OR BLISTER AGENTS

BACKGROUND

Blister agents were developed and used during the First World War as chemical warfare agents.[48,49] These agents can be used in multiple forms to include liquid, solid or gas. Blister agents are generally broken down into sulfur mustard, nitrogen mustard, and Lewisite. Although used in different concentrations and in different forms, currently sulfur mustard is the most common blister agent used on the battlefield.

Sulfur mustard has three different main forms: HD, which is a distilled product and is close to 100% pure; H, which is undistilled sulfur mustard; and HT which is a mixture of HD and T (a thickener which can be added to sulfur mustard). HD or pure mustard is clear and smells of garlic. H sulfur mustard can be clear, yellow, red brown or black depending on the chemical mixture. In recent conflicts, to include the conflict with ISIS, H sulfur mustard is the chemical seen on the battlefield. This substance, made in crude chemistry labs, is a thick oily black substance which degrades quickly, only lasting 2-3 weeks in storage before degrading beyond utility.

Nitrogen mustard is much less commonly used as a chemical warfare agent. It is separated into 3 forms: N1, N2, and N3. Nitrogen mustard can have different smells with N1 smelling more like fish, N2 like fruit, and N3 like bitter almonds. Nitrogen mustards are clear to yellow oily substances that evaporate slowly and can harm first responders by contact or off-gassing from injured victims. Used for medicinal purposes such as chemotherapy or wart removal, these agents have so far never been used on the battlefield.

Lewisite is the last vesicant in this family of chemical agents. Related to arsenic, Lewisite is a clear liquid in pure form and amber or black in impure forms. Like the other vesicants, it is extremely irritating to the skin, eyes and respiratory tract. Lewisite can be mixed with HD for a more potent chemical warfare agent with properties from both substances. Unlike the other vesicants, Lewisite is the only vesicant that has an antidote to counter its systemic effects.

SIGNS AND SYMPTOMS OF VESICANT OR BLISTER AGENTS

The most common route of exposure of all blister agents is via the skin. Sulfur mustard agents will cause chemical burns associated with blisters within a few hours of contact with the skin or mucous membranes. Effects are not seen immediately on contact, but sulfur mustard is absorbed within minutes of contact on the skin or eye membranes. Second and third degree burns develop over 2-10 hours to the eyes and skin, causing intense pain, corneal perforations, erosions of the eyes, and blistering of all exposed skin. HD had a 2-3% mortality rate during WWI, but burns in excess of 25% body surface can be fatal. Nitrogen mustard has similar effects on the skin and eyes as sulfur mustard. However, Lewisite has immediate effects on the skin and eyes causing immediate pain and irritation and blistering much sooner than HD or nitrogen mustard.

Inhalation or ingestion of these vesicants causes similar problems, damaging the mucosa of both the respiratory and digestive systems, causing severe burns. Liquid agents, which are more concentrated, cause more severe damage than vapors which might be inhaled. Much like skin and eye exposure, inhalation of HD has a delayed effect on the respiratory tract, causing wheezing and swelling of the bronchioles several hours after exposure. As with skin symptoms, Lewisite causes respiratory symptoms much faster, usually within seconds to minutes, which then rapidly progresses to pulmonary edema following exposure.

Several late effects can occur from all blistering agents depending on the dose and the route of exposure of the agent. Bone marrow suppression can occur with increased likelihood of infection, and nitrogen mustard will cause anemia. High doses of sulfur mustard can cause convulsions and hyper-excitability. High doses of Lewisite can lead to hepatic necrosis, acute renal failure, and shock via capillary leaking, referred to as “Lewisite Shock.” There are many long-term effects suspected such as malignancies, corneal scarring, chronic respiratory disease, and dermal scarring.

DECONTAMINATION OF VESICANT OR BLISTER AGENTS

Safety of the rescuers and healthcare providers is the most important initial step when handling mustard casualties. First responders should have respiratory and skin protection during initial treatment of mustard

casualties. Butyl rubber is the recommended level of protection for the hands; however, double layers of nitrile gloves will protect against exposure as well. Remember, contaminated patients may appear innocuous due to delayed onset of symptoms, however providers can still be exposed to significant injury to the lungs, eyes, and skin if not properly protected. The casualty must be decontaminated and all clothing and equipment removed; vesicants enter the body within minutes, but can stay on equipment or clothing for days after exposure.

Removal of the agent must occur within three to five minutes in order to reduce absorption. Removal with a dry cloth is the first step to clear the chemical from the skin, followed by RSDL. There is no antidote for vesicants like there is for nerve agents, so initial treatment is focused on rapid decontamination. Exposure to the eye causes faster absorption than skin and should be washed out immediately with water in order to minimize the effects. Eye wash kits with Morgan Lens can facilitate eye decontamination. It is important not to induce vomiting if there is any concern for ingestion, and activated charcoal has not been shown to be effective in these situations. After decontamination, standard burn care treatment is recommended for all dermal injuries. Fluid replacement may not follow the thermal burn estimates; however, urine output remains a good marker of adequate resuscitation and fluids should be titrated to target a urine output of 30-50 ml/hour.

Wounds which are chemically contaminated should be aggressively flushed and treated as if there is heavy contamination. Mustard enters the body systemically almost immediately after exposure to open wounds or mucus membranes. After initial decontamination, the patient should be transported to a hospital and observed for both systemic and local effects of the contaminated wound. Surgical debridement of open wounds will almost always be required for contaminated wounds.

VESICANT OR BLISTER AGENTS DIAGNOSTICS

There is no readily available test to confirm vesicant exposure. Leukocytosis is anticipated on the first day and will rise with the amount of associated injury. Subsequently, bone marrow suppression occurs and leukocyte count will fall around day 3 to 5 with a nadir seen around day 9. Counts less than 500 indicate a poor prognosis. Chest X-ray can be used to monitor for pneumonitis, which typical appears in the first 2 to 3 days.

TREATMENT OF VESICANT OR BLISTER AGENTS

For asymptomatic patients exposed to sulfur mustard and nitrogen mustard, the effects may be delayed for skin, eye, and lungs; therefore, observation of potential exposures for 6-10 hours is recommended.

Patients with eye exposure may benefit from regular application of an anticholinergic ophthalmic ointment to prevent synechiae formation. A topical antibiotic/steroid ointment should be applied every 1-2 hours with rapid referral to an ophthalmologist. Ointment application to the lids prevents them from sticking together and can help prevent adhesions while allowing drainage of any underlying infection or pus. Blepharospasm can be treated with topical anesthetics to facilitate the eye exam, and systemic analgesics should be given for ongoing eye pain.

Table 7. Vesicant or Blister Agent Intervention

Agent	Intervention	Highlights	References
Sulfur Mustard[50]	Corticosteroids	Limited animal studies, immunosuppression may be detrimental	Wigenstam 2012 [53]
Nitrogen Mustard[51, 52]	Antioxidants and scavengers (Vitamin E, N-acetyl cysteine [NAC], glutathione, sodium thiosulfate)	Limited animal studies	Vojvodic 1985 [54] Anderson 2000 [55]
	Filgrastim/pegfilgrastim	Burns >25% Body Surface Area(BSA) with bone marrow suppression	Anderson 2006 [56]
	Amifostine	May provide protection prophylactically (animal studies)	Vijayaraghavan 2001[57,58]
Lewisite	British Anti Lewisite (BAL)/Dimercaprol	Chelation agent with significant side effects	Vilensky 2003 [59, 60]

If patients have respiratory symptoms hours after the exposure, they should be treated as chemical pneumonitis; albuterol should aggressively be utilized, and invasive airway management should be considered early in the treatment plan if the patient is not responding to albuterol. Systemic steroids have been recommended if albuterol is not effective, but further immune suppression may not be advisable. Inhaled sodium bicarbonate has been suggested as a possible treatment as well, but there is not robust evidence to support its use. Other antioxidants and scavengers such as sodium thiosulfate have shown some benefit in animal studies, but there is no human data to support their use. These therapies should only be considered in patients' refractory to supportive care when the benefit of unproven therapy outweighs potential risks.

Bone marrow suppression usually peaks around 9-10 days. Granulocyte colony stimulating factor analogues may be administered. Severe bone marrow suppression may be an indication for bone marrow transplant.

The antidote for Lewisite is British Anti-Lewisite (BAL), also known as Dimercaprol. BAL should only be used in a hospital setting and is given as an IM injection. BAL is a chelating agent, but due to the possibility of severe acute renal failure and other side effects, BAL is only recommended for patients who have severe respiratory symptoms or Lewisite shock.

INCAPACITATING AGENTS

BACKGROUND

Incapacitating agents produce temporary physical and/or mental effects that result in the inability of the affected individual to continue in their current duties or activity. Often they are described as non-lethal agents, but if administered in high enough doses, incapacitating agents can results in death or serious morbidity. There are three general categories of incapacitating agents:[61]

1. Anticholinergics

BZ (3-quinuclidinyl benzilate) is the prototypical anticholinergic agent but other anticholinergic agents may be developed for warfare. The British reportedly have a similar agent known as Agent 15. BZ is a centrally acting anticholinergic agent that was originally developed as a gastrointestinal antispasmodic but due to severe central nervous system effects was abandoned as a pharmaceutical. As an incapacitating agent, it has a very high safety profile due to the relatively lower peripheral antimuscarinic effects when compared to atropine. An effective incapacitating dose is 0.5 mg, and BZ is typically dispersed as an aerosol or in smoke-producing munitions.

2. Sedating agents

Opioids and volatile anesthetics are both potential sedative or calming agents. Fentanyl is a synthetic opioid with 100 times the potency of morphine. Newer derivatives of fentanyl are continuously in development. One such example is carfentanil with a potency 100 times fentanyl. While these agents are highly effective in individuals, aerosolizing them to use as an incapacitating agent can be problematic. It is likely that absorption in a crowd would be variable.

3. Riot control agents

Riot control agents, also known as harassing agents, cause irritation and discomfort often in the form lacrimation, mucous membrane irritation, violent coughing, or vomiting. Typical agents include chloroacetophenone (CN) commonly known as Mace, chlorobenzylidene malononitrile (CS), oleoresin capsicum (OC) called pepper spray, and diphenylaminochloroarsine (DM) or Adamsite. CN is more harmful than the other agents with a lower LCt50 and DM tends to cause vomiting.

SIGNS AND SYMPTOMS OF INCAPACITATING AGENTS

Anticholinergics

BZ is intended to target CNS effects, therefore anticholinergic delirium will be the predominant symptom with fewer peripheral effects. Often the patient cannot give a lucid history due to delirium. The delirium may be labile and can range from mild impairment to coma. Hallucinations, severe agitation, and even seizures may occur. The classic peripheral effects often described a “dry as a bone, hot as a hare, red as a beet, and blind as a bat” may be variable or delayed.

Sedating agents

Sedating agents which are opioid derivatives can be expected to present with the classic opioid toxidrome of miosis, CNS depression, and respiratory depression. Bradycardia, hypotension, and hypothermia may occur as secondary sequelae as a result of dose-related progression to opioid coma.

Riot control agents

Riot control agents can be expected to affect the skin, respiratory system and eyes. Ophthalmologic symptoms include pain, tearing, and blepharospasm. The respiratory tract can be variably affected and

symptoms may range from mild mucous membrane irritation to severe dyspnea, coughing and chest tightness. Bronchospasm is common and may be severe in those with underlying reactive airway disease. Copious rhinorrhea and salivation may occur and clinical scrutiny is necessary to exclude the possibility of nerve agent exposure. Dermatologic effects typically involve skin pain and burning, but blistering may occur at higher doses.

GENERAL MANAGEMENT

Safe removal from exposure is the priority. Respiratory protection for providers in a potential exposure area is critical. Once the casualty is removed from the exposure area, decontamination can be continued with removal of all clothing and personal effects. Simple soap and copious water are adequate for through decontamination. Recognize that improvement in symptoms caused by riot control agents may be transient with decontamination.

Medical management of all incapacitating agents is predominantly supportive with attention to symptoms and tailoring treatment to the patient presentation.

ANTICHOLINERGIC AGENTS

Patients with anticholinergic toxicity can present with dry mouth and tachycardia leading the provider to believe dehydration is present when the patient is euvolemic. However, psychomotor agitation and hyperthermia are common so careful monitoring of core temperature, volume status and urine output is important. Cooling should be undertaken promptly when hyperthermia is present.

Pharmacologic managements include control of delirium and agitation. Agitation can be safely controlled with a benzodiazepine titrated to effect. Often controlling the agitation will also improve tachycardia and hyperthermia. Physostigmine is also an option to manage the delirium. This is a tertiary amine which crosses the blood-brain barrier. Before using physostigmine, it is critical to exclude the presence of other sodium channel blocking agents such as tricyclic antidepressants. An EKG should be done to ensure a normal QRS interval <100msec prior to physostigmine use, which limits its utility when EKG is not immediately available. Additionally, atropine should be ready in case there is a cholinergic response that affects the airway. In most cases, benzodiazepines are considered the primary treatment option since they can be administered safely to almost any patient.

SEDATING AGENTS

Support of the respiratory system is the primary focus for treatment of opioid toxicity associated with sedating agents. Naloxone is the antidote of choice and should be titrated to reverse respiratory suppression. Nasal naloxone can be rapidly administered without IV access. Naloxone should be titrated to effect. A starting dose of 2-4 mg is appropriate but much higher doses may be required to reverse the effects of synthetic opioids. The half-life of naloxone may be shorter than the half-life of the agent and repeat dosing or a naloxone drip may be necessary.

RIOT CONTROL AGENTS

Most riot control agents are short acting and supportive care is usually adequate until symptoms subside.

INCAPACITATING AGENT DIAGNOSTICS

Laboratory values are of little diagnostic utility. Opioids may be detected on routine toxin screen.

INCAPACITATING AGENT TREATMENT

Advanced interventions and the supporting evidence are described in the table below.

Table 10. Interventions for Incapacitating Agents

Agent	Intervention	Clinical Notes	References
Anticholinergic agents, BZ	Benzodiazepines	Control agitation and autonomic activity, seizure prevention/ treatment	Burns 2000[62]
	Physostigmine	Useful to reverse anticholinergic delirium, must have normal QRS on EKG, need atropine on hand if cholinergic crisis ensues	Burns 2000[62] Wetherall 2002[63]
Opioids	▪ Naloxone Initial dose of 2-4 mg followed by doubling escalating doses (4mg, 8mg, 16 mg) ▪ Narcan drip at 2/3 response rate ▪ Recognize half-life of naloxone may be shorter than some agents so may need re-dosing	Extrapolated from pharmaceutical opioid experience	Boyer 2012 [64]
Riot control agents	Sodium metabisulfite	Neutralizes malononitrile (CS)	Schep 2015 [65]

ACRONYM DEFINITIONS

ACLS: Advanced Cardiac Life Support
AP4C: Handheld Chemical Decontamination Device
AP-PPE: All-purpose Personal Protective Ensemble
ARDS: Acute Respiratory Distress Syndrome
CANA: Convulsive Antidote Nerve Agent
CCP: Casualty Collection Point
Cl: Chlorine
COCL2: Phosgene
CRESS: Consciousness, Respirations, Eyes, Secretions, Skin
CWA: Chemical Warfare Agents
DMSA: Dimercaptosuccinic Acid
FDP: Freeze-dried Plasma
FWB: Fresh Whole Blood
HPMK: Hypothermia Management Kit
ICP: Intracerebral Pressure

IDLH: Immediately Dangerous to Life or Health

JLIST: Joint Lightweight Integrated Suit Technology

LCD: Lightweight Chemical Detector

LCt50: Lethal Concentration, 50%;

LD50: Lethal Dose, 50%

MDI: Metered Dose Inhaler

MACE: Military Acute Concussion Evaluation

MOPP: Mission Oriented Protective Posture

MSS: Mission Support Site

NS: Normal Saline

PEEP: Positive End Expiratory Pressure

PFC: Prolonged Field Care

PPE: Personal Protective Equipment

RSDL: Reactive Skin Decontaminant Lotion

SIRS: Systemic Inflammatory Response Syndrome

TBI: Traumatic Brain Injury

TIC: Toxic Industrial Chemical

TIM: Toxic Industrial Material

TXA: Tranexamic Acid

UIPE: Undergarment Integrated Protective Ensemble

USAMRICD: US Army Medical Research Institute of Chemical Defense

APPENDIX A: ATROPINE/SCOPOLAMINE PROTOCOL

Items Needed for One Casualty

(2) Vials 0.4mg/mL Scopolamine
(1) 3mL syringe
(1) 18ga hard needle
(1)250 mL Bag of NS.
(3) Vials 8mg/20mL Atropine
(1) Micro drip dial-a-flow.
(1) Pressure Infuser
(1) FAST One IO device w/ Flush or IV access kit

Preparation

If anticipating Nerve/Organophosphate/Carbamate exposed patients:

Prep Scopolamine as follows:

1. Draw 0.8mg (2mL) of scopolamine from the 0.4 mg vials into one 3mL syringe.
2. Leave syringe complete with a capped 18 ga needle so that it is ready for rapid administration.
3. Label syringe conspicuously with "SCOPE 0.8mg/2mL"

Prep Atropine drip bag as follows:

1. Add 50 mL of 8mg/20mL Atropine to 250 mL bag of NS.
2. Bag is now 20 mg/300mL. Ensure no air is in the bag as the extra 50 mL may barely fit.
3. Conspicuously mark bag w/ "ATROPINE 20mg/300mL approx. 1mg/3min"

Administration

After the administration of 3 ATNAA and 1 CANA IM assess patient and if not improved, administer scopolomine (preferred) OR atropine per the following protocols:

- If inadequate response to 3 ATNAA and 1 CANA, administer 0.8mg Scopolamine hydrobromide via IV/IO and flush. IM as a secondary.

OR

- Give bolus dose atropine in escalating doses every 3-5 minutes. Start with 2mg followed by 4mg, 8mg, 16mg.
- Once symptom control is achieved, start an atropine drip prepared as outlined above with a dose rate at 10% of the bolus dose (including the 6mg of atropine in the 3 initial ATNAAs) per hour.
- If a rebolus is required to control recurrent symptoms, then increase the drip to 20% of the initial response dose.
- Scopolamine 0.8mg is approximate to Atropine 10mg when calculating the initial response dose.
- A drip rate to 300 mL/hr this will administer approximately 1mg of atropine every 3 min.

Note: This protocol is intended to use as a starting point for providers who do not routinely use these medications. The protocol should be reviewed by physicians supervising non-licensed providers. This protocol does not supersede the clinical judgement of the responsible provider.

Sequence of actions in nerve agent exposure should be as follows:

- 3xATNAA
- 1xCANA
- IO access
- 2gTXA (if concomitant trauma)
- 500mg 2PAM IO/IV push (15-20 min improvement)
- 0.8mg scopolamine IO/IV
- Atropine 2mg IO/IV followed by doubling escalating doses q3-5min
- (if no change in mental status even if dry/atropinized) Midazolam 10mg for subclinical seizures
- 2 PAM drip IV

Naloxone:

- Initial dose of 2-4mg followed by doubling escalating doses (4mg, 8mg, 16mg)
- Narcan drip at 2/3 response rate

APPENDIX B: PRALIDOXIME (2-PAM) DRIP PROTOCOL

Pralidoxime (2-PAM) Drip Protocol

**given after 1800mg IM Injection (3 ATNAAs) if symptoms persist.*

1. Reconstitute 1 gram 2-PAM with 20mL of sterile water
2. Add 10mL 2Pam (500mg) to 100 mL Bag of NS and infuse over 5 minutes
3. Prepare continuous infusion by mixing 1 gram (20mL reconstituted) in 100mL bag of NS which will provide a 10mg/mL solution. Can also prepare 10 grams in 1L NS for a 10mg/mL solution.
4. Begin continuous infusion at 10mg/kg/hr.

APPENDIX C: PULMONARY AGENTS INHALATION INJURY TREATMENT PROTOCOL

Pulmonary Agents Inhalation Injury Treatment Protocol

Symptom relief for cough and wheezing/reactive airways

Albuterol nebulize 2.5mg in 3mL
Can combine with 3mL 4% or 2% lidocaine (for cough / pain suppression prn)
only use lidocaine in alert casualty

Note: The following treatments do not have robust evidence to support use but may be considered in patients with moderate to severe symptoms that are refractory to supportive care.

Nebulized Bicarbonate + N-acetylcysteine (NAC)

3mL 4.2% Bicarb (1.5 mL 8.4% diluted in 1.5mL Sterile Water) combine w/ 3mL NAC (for acidic inhalation, do not mix with other drugs or use if non-acidic inhalation)

Albuterol + NAC

Albuterol 2.5mg in 3mL combined with 3mL NAC (may repeat q 4-6 hrs)

Corticosteroids

Inhaled (can nebulize or use inhalant device) :
Budesonide 0.5mg-2.0mg BID
or
Fluticasone 200mcg BID

Administration via IV/IO:
Dexamethasone 8mg IV/IO q6hrs
or
Solu-medrol 125mg IV/IM q6hrs

APPENDIX D: EYE INJURY TREATMENT PROTOCOL

Toxic Industrial Chemical/Toxic Industrial Material/Vesicant Eye Injury Treatment Protocol

Tetracaine Eye Drops for Pain

1. 20 min normal saline flush with Morgan's Lens (LR is appropriate for Acids)
2. Ophthalmic antibiotic ointment to prevent eyelids from sticking shut
3. Allow eyes to drain. Avoid tight bandaging.

APPENDIX E: SEVERE VESICANT INHALATION PROTOCOL

Severe Vesicant Inhalation Protocol

- Mustard symptoms will be delayed, if severe airway complications arise it will most likely be during PFC. Lewisite injury will be immediate.
- Deep Tracheal Suctioning, Bronchoscopy, RSI, and Mechanical Ventilation also may be required.
- IV/IO 8mg Dexamethasone (preferred) or 125 mg Solu-Medrol
- Albuterol + NAC + Lidocaine

  Combine in a nebulizer q 4-6 hrs:

  (1) Albuterol bullet, 2.5mg in 3mL ,

  (2) NAC 20%, 3mL

  (2) Lidocaine 4% or 2%, 1 mL

Complications & Adverse Effects: Lidocaine can create an airway protection issue if casualty has altered level of consciouisness.

There is a potential for pneumonitis to develop after vesicant lung injury. Antibiotics (azithromycin, levofloxacin or moxifloxacin), should be used in the setting of suspected infection and not prophylactically

APPENDIX F: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Chemical, Biological, Radiological and Nuclear (CBRN) Injury Part I: Initial Response to CBRN Agents (CPG ID: 69)

This guideline is intended for use in conjunction with Tactical Combat Casualty Care (TCCC) guidelines as an organized approach to the care of chemical, biological, radiological and nuclear (CBRN) casualties in the deployed environment.

INTRODUCTION

This Role 1 (including Point of Injury [POI]) through Role 3 Clinical Practice Guideline (CPG) is intended for use in conjunction with Tactical Combat Casualty Care (TCCC) Guidelines. This CPG is meant to provide medical professionals who encounter CBRN exposures with evidence-based guidance where it exists or consensus opinion when evidence is lacking. This CPG is divided into 4 sections:

1. Response to CBRN agents (an approach to all CBRN casualties)
2. Medical management of chemical agent exposure
3. Medical management of radiation exposure and nuclear events
4. Medical management of biologic agent exposure

While encountering conventional casualties on the battlefield remains a more likely scenario, vigilance is necessary for unusual scenarios that might represent the first clue that a CBRN incident occurred. Since environmental sampling for agent detection and rapid point-of-care testing for agent identification will not be routinely available in austere environments or most hospital settings, the initial suspicion of a CBRN attack will rest on clinical recognition of signs and symptoms of poisoning. This guideline is intended to provide an approach to casualty assessment and treatment from POI to established medical facilities.

BASIC PRINCIPLES OF CBRN CASUALTY MANAGEMENT

Initial care of the CBRN casualty should be approached in the same manner as other casualties. Life threats require prompt recognition and intervention, and non-life-threatening sequelae can be addressed when clinically appropriate. Early recognition and categorization of CBRN-exposed patients is the foundation for further management, and is key not only for initiating patient treatment but also for preventing contamination of medical personnel, equipment, and facilities. Thorough and appropriate decontamination is a core skill that requires planning and practice. Attention to details such as preventing hypothermia in patients undergoing decontamination and clinical reassessment at each stage of the process will reduce unnecessary morbidity. Basic life saving measures such as airway management and resuscitation are fundamental concepts that must be mastered at the appropriate level for each practitioner in the CBRN care chain. Furthermore, easy access to reference materiel to guide advanced therapy should be a part of every provider's armamentarium. These basic principles will be discussed in more detail in the sections that follow.

CRITICAL TASK LIST

The critical task list is applicable to both medical and non-medical personnel. All personnel should be trained on the concepts and principles identified in the critical task list in order to respond to CBRN casualties. The critical task list addresses core competencies that can be adjusted based on the medical skill level of the responder. These tasks should be trained according to service-specific publications and recognized standards of medical care.

- Recognize CBRN exposure that requires action to protect self and others
- Don personal protective equipment (PPE) to prevent exposure in self and assist others with PPE
- Egress from the threat
  - Move upwind, uphill, upstream from threat
  - Utilize time/distance/shielding for protection

- Recognize signs/symptoms of CBRN exposure that prompt immediate self-treatment or treatment of others (i.e. nerve agent exposure)
- Apply TCCC integrated with CBRN response TCCC + CBRN = (MARCHE)[2]

  Massive hemorrhage/mask, airway/antidote, respiration/rapid spot decontamination, circulation/ countermeasure, hypothermia/head injury, extraction/evacuation
- Apply airway management skills in a CBRN setting (positioning, suction, ventilation to include manual and mechanical, placement of definitive airway)
- Perform Rapid Spot Decontamination
- Identify and establish Hot/Warm/Cold Zones
- Establish a dirty casualty collection point (CCP)
- Understand decontamination principles and casualty procedures for partial or complete removal of PPE, clothing, and equipment (casualty cut out)
- Understand cross contamination and take appropriate measures to prevent it
- Understand available technology that can aid in agent identification

PLANNING CONSIDERATIONS

The response to CBRN exposure requires extensive planning based on the threat. In a high-threat environment, immediate availability of adequate PPE is essential. Personnel should also be aware of field expedient PPE options. (Table 1)

Table 1. Examples of Military-issued PPE

Examples of PPE –Military Issued	
Respiratory	• M50 Joint Service General Protective Mask (JSGPM) • M61 filter, C2A1 canister • M40/ M45, M53 Mask
Skin	• Joint Service Lightweight Integrated Suit Technology (JSLIST) Chemical & Biological Protective Garment (24 hour protection) • All-purpose-Personal Protective Ensemble (AP-PPE) • Lion Extended Response Team (XRT) Suit (8 hours protection) • Butyl rubber gloves with cotton liner • Vinyl overboot

Table 2. Field Expedient PPE Alternative

Field Expedient PPE Options When CBRN-Specific Equipment Not Available	
Respiratory	Emergency Passenger Oxygen System (EPOS)
Skin	Nitrile gloves x 3
Equipment	6mm sheeting and bags

EVACUATION PLANNING CONSIDERATIONS

MEDICAL REGULATING

1. Military Treatment Facility (MTF)
   - DECON/Treatment Coordination. Ensure MTF is prepared to receive dirty casualties and determine the most appropriate location for DECON.
   - Treatment Capabilities (Toxicology, Critical Care, Trauma Surgery). Determine whether the MTF has the services necessary to care for and sustain the CBRN casualty on site and/or establish telemedicine support.
   - Capacity. The CBRN casualty is far more resource intensive than a typical trauma or critically ill casualty. Assess the MTF's capacity and capability to treat CBRN casualties and identify potential alternate locations.
2. Evaluation. Integrate the medical regulating system into CBRN exercise scenarios.

LANDING ZONE / CASUALTY EXCHANGE POINTS

1. Route coordination.
   Consider alternate routes, primary routes may be jammed or unavailable.
2. Environmental Considerations
   - Wind
   - Terrain / Slope
   - Drainage
   - Water sources

EVACUATION PLATFORMS

1. Clean and Dirty. It is necessary to plan for both clean and dirty platforms for evacuation.
2. Refuel. When planning evacuations, consider the time it takes for refueling in a MASCAL situation, as well as the distance from the objective to the DECON site and MTF. Also factor in any platform decontamination that may be necessary prior to arrival at the refueling site.
3. Aircraft/Vehicle DECON (Spot, Wash Down, Detailed). Based on the available assets, determine the time it will take to conduct each type of decontamination.
4. Preparation time (hasty vs. deliberate). Factor the time it takes to prepare the platform for a hasty or deliberate CBRN mission.
5. Evaluation. Integrate evacuation and handoff training into CBRN training exercises.

PROTECTIVE MEASURES

(allow for time required to install when planning)

1. Barrier (disposable; plan for additional on-hand quantities)
   - Preventive maintenance checks need to occur on a regular basis.
   - Consider time required for deliberate vs. hasty set-up.

- 6mm tarp and chemical or 100-mph tape for improvised

2. PPE (Pilots / Drivers / Crew)

CASUALTY CARE

Class VIII (medical supplies) and critical care support equipment:

1. Antidote and countermeasure resupply and additional stock (information on the CDC's Strategic National Stockpile can be found at https://www.cdc.gov/cpr/documents/dsns_fact_sheet.pdf)
2. Airway support / ventilation - anticipate need for advanced airway management and ventilators
3. Casualty Monitoring
   - Electronic vital signs monitoring
   - ETCO2
   - Hypothermia. Special emphasis must be placed on maintaining body temperature, as cut-out procedures will create greater exposure to environmental factors.

DECONTAMINATION

An extensive discussion of decontamination is outside the scope of this CPG, however basic decontamination principles are outlined below. (Figure 1)

1. Prevent further casualties by applying PPE before treating others.
2. Remove all clothing and equipment. Contain and dispose of contaminated material appropriately.
3. If radiologic exposure, cover wounds before further decontamination. Ensure gentle decontamination as radionuclide absorption may be increased if skin becomes erythematous.
4. Decontamination solutions
   a. Soap and water in copious amounts
      - Physical removal and dilution of agents
      - Does not destroy biological agents or neutralize radioactive particles
   b. 0.5% hypochlorite solution
      - Nine parts water to one part 5% bleach
      - Wipe on the skin and rinse with fresh water
      - Can be used in open wounds but do not use in chest or abdominal cavity (risk of adhesions), open brain or spinal cord wounds (unknown effects), or in the eyes (risk of corneal opacification)
   c. Reactive Skin Decontamination Lotion (RSDL)
      - Indicated for chemical agents and T-2 mycotoxin
      - Packaged sponge contains reactive agent that penetrates skin
      - Deactivates mustard (HD) and nerve agent

- Currently FDA-approved only for intact skin, not for wounds or eyes
- Best results occur when RSDL is applied immediately after exposure, gently scrubbed (agitated) on skin for two minutes, removed, and then reapplied (RSDL may be left on skin for up to 24 hours)

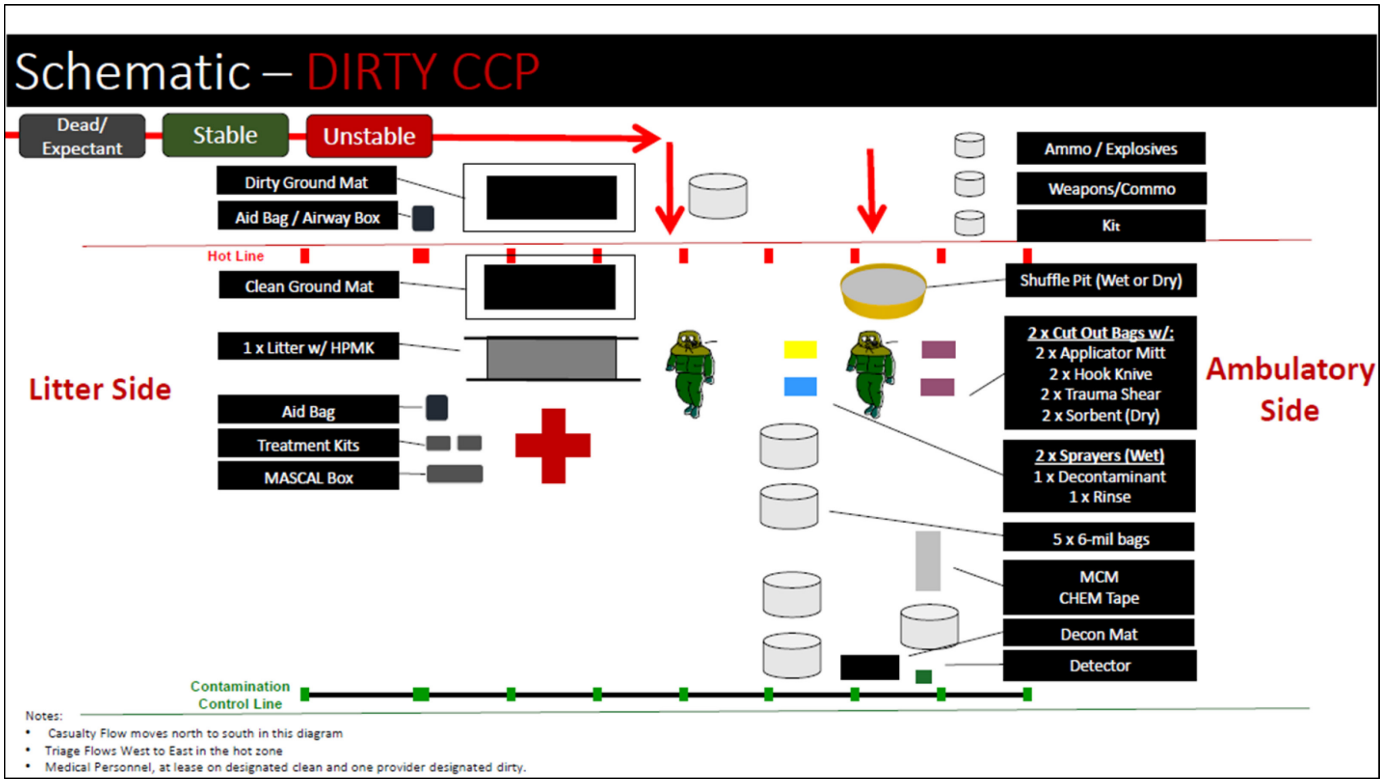
d. Surgical solutions for open chest and abdominal cavity wounds

e. Water, normal saline, or eye solutions are recommended for the eye

5. Standard infectious disease protective measures should be utilized for biological agents

6. Internal decontamination will be discussed in detail in the medical management of radiologic exposure and nuclear events

Figure 1. Casualty decontamination schematic.



Notes:

- Casualty Flow moves from top to bottom in this diagram
- Triage flows immediate to delayed from left to right in the hot zone diagram
- Medical personnel, at least one provider designated clean and one provider designated dirty

IDENTIFICATION OF AGENT

Agent identification is a critical step in determining casualty treatment. Recognize that intelligence reporting may be incomplete or inadequate. There are a variety of detectors that can aid in agent identification and providers should be familiar with the technology that is part of their organization.

Combine available intelligence, technology, and patient presentation to create a comprehensive picture for agent identification to help guide treatment. Mixed exposures are possible and correlating patient signs and symptoms with adjunctive agent identification techniques can help ensure the proper treatment is pursued.

** Casualty treatment should never be delayed pending confirmatory agent identification. Clinical assessment (using CRESS described below) is necessary to determine immediate therapy. Decisive efforts for agent identification can be done in parallel to timely medical treatment.**

TRIAGE AND EVACUATION PRIORITIES

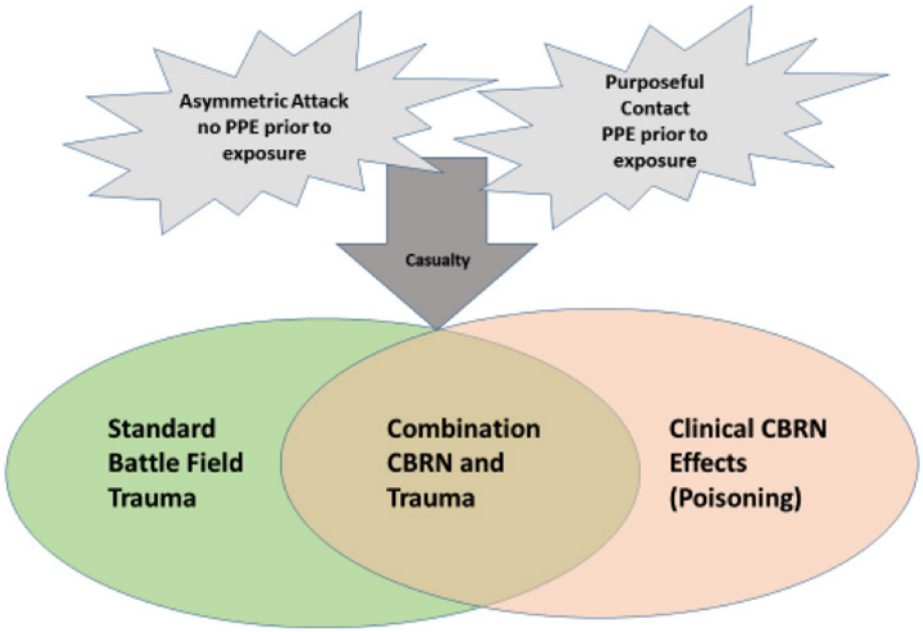
Because of the differences in casualty presentation for chemical, biological, radiological, and nuclear event casualties, specific triage recommendations and evacuation priority considerations will be addressed in the portion of the CPG that is specific to the categories of CBRN exposures.

Do not forget that CBRN exposure is an enemy attack and security will be the first priority to be coordinated. Then, triage for a CBRN event follows established triage principles, including doing the most good for the most people. Because of the complexity of combined CBRN and trauma casualties, it may be beneficial to assign an experienced provider to triage. Triage occurs for decontamination, for medical treatment, and for evacuation. Although placing casualties into one of two groups for assignment to ambulatory vs. non-ambulatory decontamination lanes is a kind of sorting, true triage for decontamination involves a determination of who can tolerate delays in decontamination. Decontamination order may be based on extent of exposure and not on initial symptoms, as symptoms may be delayed. Those with more extensive exposures may benefit from rapid decontamination to decrease their risk for later symptoms, and thus reduce the future burden on medical resources. Once decontaminated, patients are triaged according to medical priority. Decontamination is a medical intervention (it minimizes or eliminates the conversion of an external dose to an internal dose), and any casualty with an area suspicious of having been exposed to a liquid chemical agent is automatically medically triaged as immediate until immediate (local, spot) decontamination has been accomplished. The casualty is then re-triaged. Except for vesicant casualties, those exposed only to vapor can tolerate delays in decontamination or may not even require thorough decontamination. It is important to frequently reassess patients. Because many CBRN agents cause delayed symptoms, a casualty initially determined to be minimal may become immediate. (Ramesh 2010) Remember that the process of decontamination can significantly change the casualty status. It is critically important to monitor for hypothermia, disruption of previously controlled bleeding, and other changes in patient status that would change triage priority.

TACTICAL COMBAT CBRN CASUALTY CARE +CBRN

Assessment and management of CBRN casualties is complex because it involves not only life-threatening symptoms (some of them rapid onset) but also the threat of contamination of all first responders. An added source of complexity is the frequent mixing of CBRN and penetrating trauma injuries. (Figure 2) Working through this complexity involves a stepwise approach that first rules in or rules out CBRN injuries so that first responders can protect themselves if necessary before rendering aid. The next step integrates assessment and management of both CBRN and traumatic injuries, prioritizing the recognition and management of life-threats first.

Figure 2. CBRN Casualties.



CRESS: A SIMPLIFIED APPROACH TO CBRN CASUALTY ASSESSMENT

A tool to rapidly evaluate for CBRN injuries is the CRESS algorithm. (Table 2)

After using the CRESS algorithm to rule out or rule in a CBRN injury, and first responders donning PPE if present, the (MARCHE)[2] algorithm should be applied to evaluate for and manage CBRN and traumatic injuries.

Table 2. Chemical casualty assessment

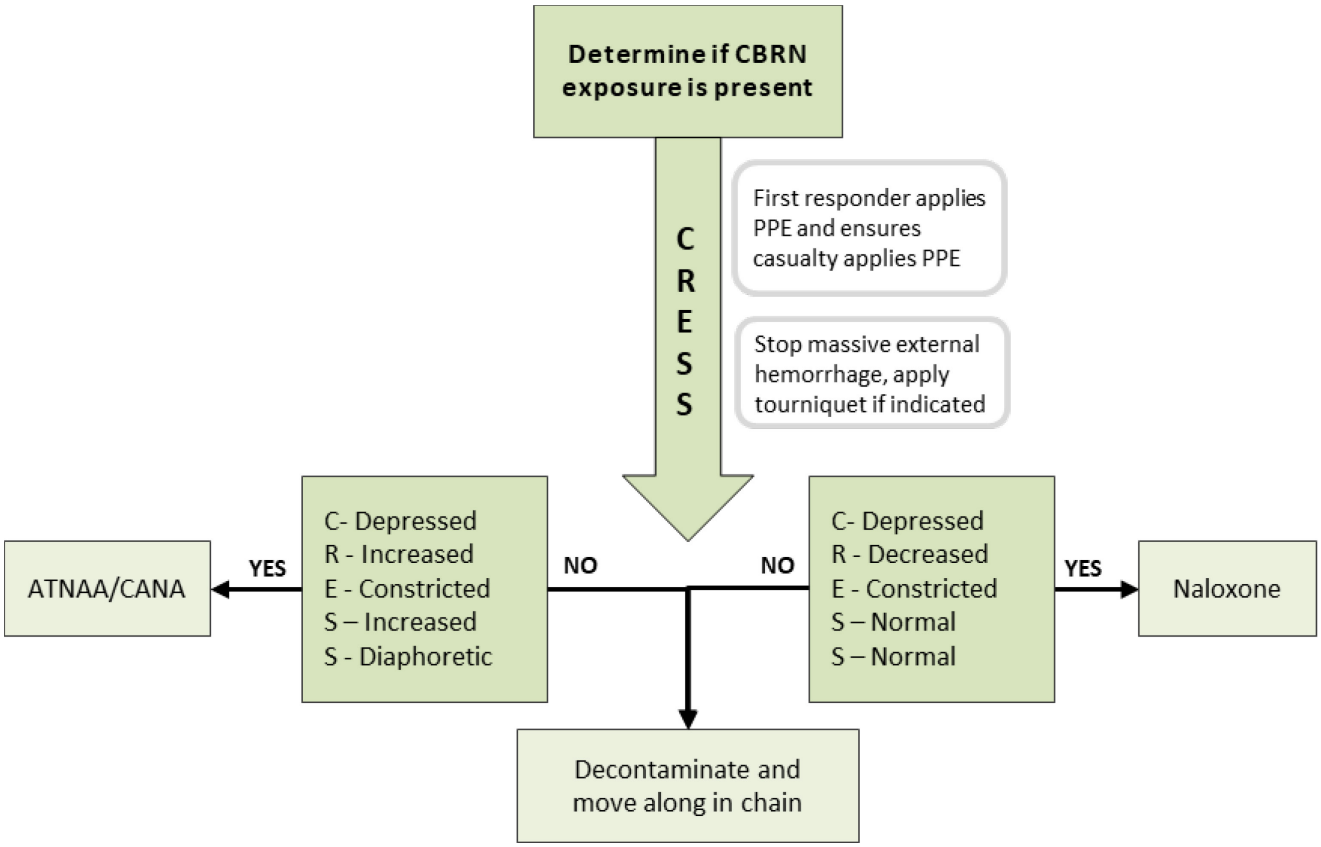
C	**C**onsciousness (unconscious, seizures, depressed consciousness, agitation)
R	**R**espirations (present or absent, labored, increased or decreased)
E	**E**yes (constricted, dilated, normal)
S	**S**ecretions (dry, normal, increased)
S	**S**kin (diaphoretic, dry, hot, cyanosis)

Just as trauma casualties present differently (blunt, trauma, GSW, blasts, etc.), CBRN casualties also have varied presentations. For example, chlorine casualties will require more attention to the toxic inhalation symptoms contrasted with a mustard casualty whose associated trauma may require more prompt intervention than the mustard-specific effects. CBRN casualties can be categorized by circumstances of exposure and presence or absence of trauma and CBRN effects. The acronym CRESS (Consciousness, Respirations, Eyes, Secretions, Skin) is employed to improve rapid identification of the type of chemical agent exposure.

In a CBRN-threat environment, casualties may have traumatic, CBRN or mixed injuries. Before applying TCCC, it is important to identify whether CBRN injuries are present and identify a suspected agent to allow first responders to protect themselves before treating the patient. While this often can be deduced using intelligence reports, technologic agent identification resources, and circumstances of the CBRN event, there will be times when agent identification will need to be made solely based on clinical assessment of symptoms. Some CBRN agents, such as nerve agents, can be rapidly fatal; therefore, recognition of such symptoms is the equivalent of identifying massive hemorrhage in the trauma patient. Clinical clues can be aggregated to identify the most likely agent responsible for symptoms according to the CRESS assessment. Each letter in CRESS corresponds to physical exam findings that can be used to categorize the suspected agent based on the constellation of findings. CRESS findings associated with specific chemical agents are shown in Table 3.

Figure 3. The acronym CRESS

The acronym CRESS is used to differentiate exposures to chemical agents. Exposure to biological agents is unlikely to cause early symptoms. Radiologic exposure may lead to early onset of symptoms (<1 hour post exposure) such as nausea, vomiting, diarrhea, and fever with high dose exposures (>6 Gray). CRESS findings for select chemical agents are summarized in Table 3.



.

Table 3. CRESS finding for select chemical agents.

Agent	Consciousness	Respirations	Eyes	Secretions	Skin
Nerve	Depressed consciousness or unconscious	Increased	Constricted (Miosis)	Increased (lacrimation, rhinorrhea, salivation, bronchial secretions)	Diaphoretic
Cyanide	Depressed consciousness or unconscious	Increased	Normal	Normal	May be flushed or cyanotic when advanced shock
Chlorine Phosgene (delayed effects)	Normal (unless asphyxia causes loss of consciousness)	Increased	Normal	Increased (Lacrimation, rhinorrhea, salivation) Delayed fluid in lungs	Normal
Vesicants	Normal	Increased if vapor	Normal	Increased (lacrimation, rhinorrhea, salivation) Delayed fluid in lungs at very high doses	Normal initially
Opioid Incapacitating agent	Depressed consciousness or unconscious	Decreased	Constricted (Miosis)	Normal	Normal
Anticholinergic Incapacitating agent	Agitated	Normal or increased	Normal or dilated (mydriasis)	Decreased	Dry and hot
Riot control agents	Normal	Normal or increased	Normal	Lacrimation, rhinorrhea, salivation.	Normal

(MARCHE)^2: INTEGRATING TCCC MARCH WITH CBRN FIRST RESPONSE

After initial assessment of casualty in CBRN-threat environment for the presence or absence of CBRN symptoms using the CRESS algorithm (and donning of PPE by first responders if present), the integrated assessment and management of TCCC and CBRN injuries can proceed.

The acronym (MARCHE)^2 integrates these two processes using the established TCCC MARCH algorithm (Massive Hemorrhage, Airway, Respirations, Circulation, Hypothermia) with CBRN priorities of Mask, Antidotes, Rapid spot decontamination, Countermeasures, Extraction and Evacuation. Combining these two approaches gives the acronym (MARCHE)^2 or "MARCH-squared."

Similar to TCCC, (MARCHE)^2 can be broken into phases of care from highest threat (care under fire or active CBRN threat), to intermediate threat (tactical field care or warm zone casualty management), to lowest threat (PFC/evacuation or care of decontaminated casualties in cold zone). Figure 4 below.

Figure 4. (MARCHE)²

MARCHE: Massive hemorrhage/Mask, Airway/Antidote, Respiration/Rapid spot decontamination, Circulation/Countermeasure, Hypothermia/Head injury, Extraction/Evacuation. CRESS: Consciousness, Respirations, Eyes, Secretions, Skin.

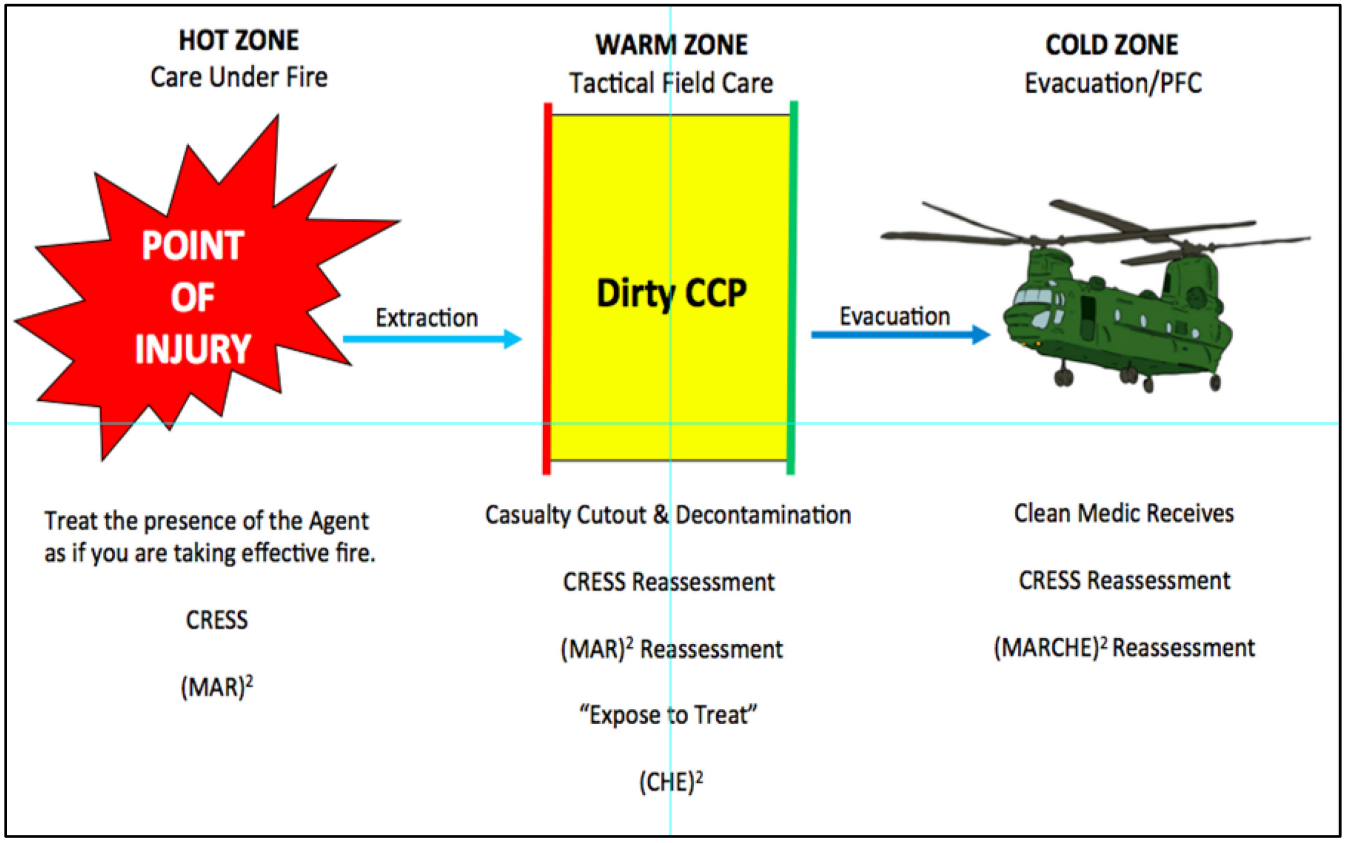


Figure 5. Hot Zone/Care under fire immediate threats.

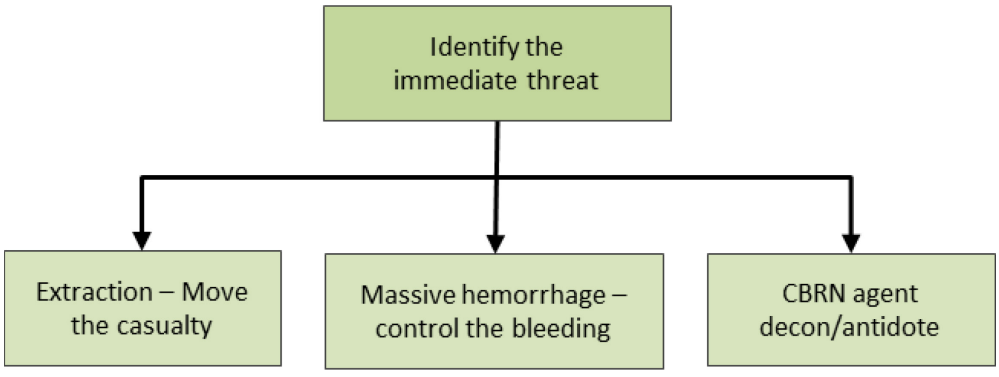

Identify the immediate threat
Extraction – Move the casualty
Massive hemorrhage – control the bleeding
CBRN agent decon/antidote

PUTTING IT ALL TOGETHER, INTEGRATING CRESS AND (MARCHE) [2]

Step 1: Hot Zone / Care Under Fire

During "hot zone" care, the agent itself is similar to enemy fire. As such, the priorities are protection from and egress away from the threat (CBRN agent) for both casualty and provider. Both casualty and provider should don protective mask. If the casualty is incapacitated, the provider must ensure the casualty's protective gear is applied and functional.

Only rapid interventions for immediate life-threats should be addressed. Massive hemorrhage, if present, may be the most immediate life threat and control of hemorrhage supersedes other interventions. Massive hemorrhage, if compressible, should be treated according to TCCC guidelines with limb tourniquets.

Perform a rapid assessment of the airway and respirations. Excessive secretions and increased respirations may indicate nerve agent exposure. Completion of the CRESS assessment will help determine if the symptoms are due to trauma or chemical agent exposure. Most airway and respiration interventions should be deferred. Occasionally, such interventions may take priority over mask application, but the decision to unmask a casualty in order to provide the intervention needs to be weighed against the risk of the contaminated environment.

Some CBRN agents are rapid killers. The CRESS assessment will quickly determine whether immediate antidotes are required. If nerve agent exposure is suspected (decreased level of consciousness, increased respirations, constricted pupils, increased secretions, diaphoretic skin) then the provider should direct self-administration of Antidote Treatment Nerve Agent Auto-injector (ATNAA) and Convulsant Antidote for Nerve Agent (CANA) or administer the antidotes for an incapacitated casualty.

Rapid spot decontamination of skin or wounds is indicated when there is gross contamination on the skin or wounds or when protective gear is breached. If wound contamination with chemical agent is suspected, immediately expose the wound to perform rapid spot decontamination. This step is necessary even in a contaminated environment and may be lifesaving.

Treatment for cyanide can be considered in the hot zone, but the need to establish IV/IO access to administer hydroxocobalamin makes this a judgment call weighed against the time needed to reach the warm zone and the ongoing threat in the hot zone location. Naloxone 2 mg intramuscular or intranasal for opioid incapacitating agents may also be considered for life-threatening respiratory depression. As in TCCC, non-essential interventions should be deferred until the next phase of care.

Table 4. Point of Injury (Hot Zone) Response– (M A R)².

Point of Injury (Hot Zone) Response– (M A R)²	
TCCC	**CBRN**
Massive Hemorrhage	**Mask**
Stop life-threatening external hemorrhage if tactically feasible: • Direct casualty to control hemorrhage by self-aid if able. • Use a CoTCCC-recommended limb tourniquet for hemorrhage that is anatomically amenable to tourniquet use. • Apply the limb tourniquet over the uniform clearly proximal to the bleeding site(s). If the site of the life-threatening bleeding is not readily apparent, place the tourniquet "high and tight" (as proximal as possible) on the injured limb and move the casualty to cover.	• Don mask • Help casualty don mask or ensure proper seal if mask already in place. • Ensure Powered Air Purifying Respirator (PAPR) or Self Contained Breathing Apparatus (SCBA) is functional.
Airway	**Antidotes**
• Assess (excessive secretions may indicate nerve agent exposure) • Airway management is generally best deferred	• Antidotes are given in the Hot Zone if the casualty has symptoms of poisoning. • These agents are rapid killers: - Nerve agent (give ATNAA, CANA). - Cyanide (give hydroxocobalamin). - Pharmaceutical based sedating agent (give naloxone)
Respiration	**Rapid Spot Decon**
• Assess: normal, shallow, labored, absent? (increased respirations may indicate nerve agent exposure) • Complete the CRESS assessment and determine if caused by the agent or trauma • Respiratory intervention is generally best deferred	• At the point of injury, physical removal of the agent/rapid spot decontamination is indicated if agent can be seen on the skin, if there is suspicion of wound contamination by agent, or if there is a breach in the suit. • Apply RSDL, M100, M295, Sorbent, tech wipe, etc.
Extraction	
Egress away from the threat	

Step 2: Warm Zone / Tactical Field Care

In the warm zone, or tactical field care phase, attention is given to decontamination and reassessment of the casualty. This phase occurs at a dirty CCP (hotline) and requires personnel dedicated to triage, decontamination, and patient treatment. At this phase, interventions may have altered the clinical presentation of the casualty (e.g., the patient may have decreased secretions and reduced airway resistance from use of the ATNAA), so it is important to take into account prior interventions and changes in the clinical status of the casualty. However, the goal is to quickly transition the casualty to the cold zone for definitive care, so only life-saving treatments should be done in the warm zone.

Decontamination and treatment can be synchronous processes. Medical personnel will need to clearly communicate with non-medical personnel responsible for decontamination. "Expose to treat" is used by decontamination personnel when the provider deems it in the best interest of the casualty to remove PPE to provide life-saving medical intervention. For example, the mask may be removed and the head, face, and chest quickly decontaminated so that the provider can ventilate the casualty and insert a sternal IO if parenteral

antidotes, blood product or fluid resuscitation or countermeasures are immediately indicated. It would also be appropriate to prioritize decontamination of an arm to establish an IV or proximal humerus IO access.

Circulation should be assessed to identify external hemorrhage and shock. The provider can assess the effects of both CBRN agents and antidotes on the patient's circulatory status. As decontamination ensues, dirty treatments are replaced with clean. Due to cold water and the need to fully expose the casualty in order to conduct thorough decontamination, hypothermia is a significant risk. Ensure rapid transit through the decontamination line with careful attention to hypothermia mitigation in order to prevent iatrogenic injury from the decontamination process. Additionally, personnel working within the warm zone in full protective gear are at risk of heat injury and stressors associated with operating in PPE, which must be recognized and mitigated

Table 5. Assessment at the Dirty CCP (Warm Zone)– (M A R C H E)²

<table>
<tr><th colspan="2">Assessment at the Dirty CCP (Warm Zone)– (M A R C H E)² Treat life-threats ONLY</th></tr>

<tr><th colspan="2">Evacuation</th></tr>
<tr><td colspan="2">• Determine Evacuation Priority
• Fill out Casualty Card
• Move patient for further decontamination or to evacuation platform.
• The Dirty CCP may be far from the point of injury, necessitating exhausting casualty carries and exposing rescuers to heat injury from the burdens of PPE.</td></tr>
</table>

Step 3: Cold Zone / Tactical Evacuation Care / Prolonged Field Care

Once the decontaminated casualty has passed into the cold zone, they should be re-evaluated and receive needed interventions to include tactical evacuation or prolonged field care. The decontamination process alone can result in significant change in the casualty's condition, so re-triage and reassessment are the first priority. If a secondary survey has not been performed, it should be done immediately after re-assessment of the primary survey. Documentation throughout the phases of care is vital to facilitate information transfer as the patient transits from one phase to another. The CBRN casualty card (Appendix B) is a useful tool to ensure comprehensive documentation relevant to the CBRN casualty. In the absence of a CBRN casualty card, the TCCC casualty card is sufficient if duration of care before transfer is short and patient is relatively stable. If handoff to higher echelon of care is delayed or patient is unstable, PFC documentation will likely be necessary. (Loos 2018)

It is important to take into consideration that receiving providers at all roles of care may have minimal to no experience with CBRN patients. Communication is crucial to ensure receiving providers understand previous decontamination and care and exposures that may be suspected. This can prevent delays in patient care caused by unnecessary repetitive decontamination or redundant treatments.

Casualties that reach the cold zone have been decontaminated and are now suitable for the full spectrum of care appropriate to the clinical environment and capabilities. There are however, some unique concerns to address in a combination CBRN/trauma casualty. While thorough decontamination and complete removal of a casualty's clothing eliminates almost all debris, it is possible the casualty may have retained foreign material or contaminated dressings in wounds. Such material may pose risk to treating personnel from off-gassing or secondary contamination. Additionally, this residual contamination may represent a continuing source of exposure to the patient via a route that bypasses the normal barriers of the skin resulting in rapid systemic distribution of the agent. Larger fragments should be removed from the wound using a "no touch" technique with surgical instruments, followed by placing the material and instrument in a sealed container with hypochlorite solution, minimizing the risk to providers. When possible, the contaminated wound should be further irrigated with clean water. Providers dealing with contaminated foreign material or dressings can wear 3 pairs of nitrile gloves. The outer glove should be discarded every 20 minutes. In the absence of suspected retained debris, the fully decontaminated patient in the cold zone can be treated as all other patients at that level of care. The extent of wound care provided will depend on prehospital resources available and transport time to surgical care.

EVACUATION CONSIDERATIONS

The en route care approach to the combined CBRN/trauma casualty should not differ from POI through TACEVAC. The $(MARCHE)^2$ mnemonic provides a helpful methodology for assessing and applying critical interventions during transport. The medical provider should perform regular reassessments, recheck all $(MARCHE)^2$ interventions, and intercede where necessary; prioritizing those interventions that are life-saving. In general, physical examination capabilities are degraded during transport. These challenges are amplified in the CBRN environment when the medical provider and crew are wearing PPE. Training while in MOPP IV and practicing patient care maneuvers that may be hindered by this protective posture is paramount to successful care of the CBRN casualty.

APPENDIX A : (MARCHE)^2 SUMMARY

TCCC + CBRN = (MARCHE)^2			
	Hot Zone	**Warm Zone**	**Cold Zone**
Priorities	• Think Care Under Fire, sometimes agent is like effective fire • "What is killing the casualty now, is it the agent or trauma?" The answer to this question dictates your treatments • Triage • Treat only immediate life-threats • Expose only what is needed to save life. • CRESS assessment. Identify nerve agent exposure. • If chemical contamination of a wound is suspected, expose perform rapid spot decontamination as soon as possible • Protect yourself and the casualty from the threat: time, distance, shielding, upwind, uphill, upstream • Heat injury from operating in PPE is common and may be unrelated to the agent. • Getting to the warm zone may require prolonged movement of the casualty. • A medic caring for chemical casualties is contaminated (dirty medic) and cannot cross to cold zone with patient until decontaminated. • In conventional TCCC, only massive hemorrhage is addressed during CUF. However, some chemical agents are rapid killers. Nerve agent antidotes and rapid decontamination must be administered as early as possible.	• Think Tactical Field Care • "What is killing the casualty now, is it the agent or trauma?" The answer dictates your treatments • Triage • Provide only life-saving care, get them to the cold zone for definitive care. • Replace dirty tourniquets and decontaminate indwelling devices or replace as indicated. • Casualty may require advanced airway management and ventilator support • Perform cutout and thorough decontamination. • Perform treatments while decontamination is being conducted. "Expose to treat". • Assess circulation and administer resuscitation fluids per TCCC guidelines only if absent radial pulse • Countermeasures: administer specific treatments for life-threats as needed based on exposure and symptoms • Hypothermia is a threat due to exposure during decontamination. • Determine whether altered mental status is due to chemical agent or trauma	• Think Tactical Evacuation or Prolonged Field Care • "What is killing the casualty now, is it the agent or trauma?" The answer to this question dictates your treatments. • Triage • Anticipate and mitigate hypothermia. • Receiving medical personnel may have little to no experience with CBRN. Ensure effective patient handoff. • Clean Medic (remains on cold zone side of hot line and not exposed to contaminated casualties)

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e., "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Crush Syndrome - Prolonged Field Care (CPG ID: 58)

This Role 1 prolonged field care (PFC) guideline is meant to provide medical professionals who encounter crush syndrome in austere environments with evidence-based guidance for how to manage the various aspects of crush injury care and monitoring.

INTRODUCTION

This Role 1 prolonged field care (PFC) guideline is intended to be used after Tactical Combat Casualty Care (TCCC) Guidelines when evacuation to higher level of care is not immediately possible. A provider of PFC must first and foremost be an expert in TCCC. This CPG is meant to provide medical professionals who encounter crush syndrome in austere environments with evidence-based guidance for how to manage the various aspects of crush injury care and monitoring. Recommendations follow a "minimum," "better," "best" format that provides alternate or improvised methods when optimal hospital options are unavailable.

Crush syndrome is a life and limb-threatening condition that can occur as a result of entrapment of the extremities accompanied by extensive damage of a large muscle mass. It can develop following as little as 1 hour of entrapment. Effective medical care is required to reduce the risk of kidney damage, cardiac arrhythmia, and death.

Crush syndrome is a reperfusion injury that leads to traumatic rhabdomyolysis. Reperfusion results in the release of muscle cell components, including myoglobin and potassium that can be lethal. Myoglobin release results in rhabdomyolysis, with risk of kidney damage. Kidney damage leads to hyperkalemia and eventually cardiac arrhythmias. Calcium is taken up by injured muscle cells and this can cause hypocalcemia, contributing to cardiac arrhythmias. The risks are increased with large areas of tissue crushed (one or both lower extremities) and the length of time the casualty is pinned prior to extrication.

The primary treatment is aggressive fluid administration. Reperfusion after prolonged tourniquet application (>2 hours), extremity compartment syndrome, and severe limb trauma involving blunt trauma can also result in rhabdomyolysis by the same mechanisms as crush syndrome, and the treatment is the same.

For feedback or additional input on this CPG, please visit PFCare.org .

Telemedicine: Management of crush syndrome is complex. Establish telemedicine consult as soon as possible.

FLUID RESUSCITATION

The principles of hypotensive resuscitation according to TCCC DO NOT apply in the setting of extremity crush injury requiring extrication.

However:

In the setting of a crush injury associated with noncompressible hemorrhage, aggressive fluid resuscitation may result in increased hemorrhage. Balancing the risk of uncontrolled hemorrhage against the risk of cardiotoxic levels of potassium should ideally be guided by expert medical advice (in-person or telemedicine).

FLUIDS[1–5]

Goal: Correct hypovolemia to prevent myoglobin injury to the kidneys and dilute toxic concentrations of potassium to reduce risk of kidney damage and lethal arrhythmias.

- **Best:** IV crystalloids
  Start intravenous (IV) or intraosseous (IO) administration IMMEDIATELY (before extrication).
  Rate and volume: initial bolus, 2L; initial rate: 1L/h, adjust to urine output (UOP) goal of >100–200mL/h (see below)
- **Better:** oral intake of electrolyte solution.
  Sufficient volume replacement may require "coached" drinking on a schedule.[6]
- **Minimum:** rectal infusion of electrolyte solution.
  Rectal infusion of up to 500mL/h can be supplemented with oral hydration.[6,7]

Life-threatening hyponatremia can result from large-volume administration of plain water. If using oral or rectal fluids because of unavailability of IV fluids or access, they must be in the form of a premixed or improvised electrolyte solution to reduce this risk.[6]

Examples of mixed or improvised electrolyte solutions include the following:

- World Health Organization (WHO) oral rehydration salts (ORS): preferred
- Pedialyte® (Abbott Laboratories, https://pedialyte.com)
- Per 1L water: 8 tsp sugar, 0.5 tsp salt, 0.5 tsp baking soda
- Per quart Gatorade® (Stokely-Van Camp Inc, www.gatorade.com): 0.25 tsp salt, 0.25 tsp baking soda

MONITORING

Goal: Maintain high UOP, detect cardiotoxicity, ensure adequate oxygenation and ventilation, avoid hypotension, trend response to resuscitation. Document blood pressure (BP), heart rate (HR), fluid input, urine output (UOP), mental status, pain, pulse oximetry, and temperature on a flowsheet.

Urine Output[8,9]

Goal: UOP of 100–200mL/h. The fluid rate should be adjusted to maintain this level of UOP.

- **Best:** place Foley catheter.
- **Minimum:** capture urine in premade or improvised graduated cylinder (e.g., Nalgene® bottle [Thermo Fisher Scientific, nalgene.com]).
- Maintain goal UOP until myoglobin can be monitored and normalized.

  If UOP is below goal at IV fluid rate of 1L/h for >2 hours, kidneys may be damaged and unable to respond to fluid resuscitation.
  Consider:

Teleconsultation, if available:

- Decreasing the fluid rate to reduce risks of volume overload (e.g., pulmonary edema)
- Hemorrhage or third spacing may cause hypovolemia.
  Consider: Increasing the fluid rate

URINE MYOGLOBIN[10–13]

Goal: Monitor for worsening condition

- **Best:** laboratory monitoring of urine myoglobin
- **Better:** urine dipstick monitoring of erythrocyte/hemoglobin (Ery/Hb)[10]
  Urine dipstick Ery/Hb will be positive in patients with myoglobinuria.
- **Minimum:** monitor urine color. Darker urine (red, brown, or black), either consistently or worsening over time, is associated with increasing myoglobinuria and increased risk of kidney damage.

HYPERKALEMIA AND CARDIAC ARRHYTHMIAS

Release of potassium from tissue damage and kidney damage can result in hyperkalemia (>5.5mEq/L), resulting in life-threating cardiac arrhythmias or heart failure[14–17]

Goal: Monitor for life-threatening hyperkalemia

- **Best:** laboratory monitoring of potassium levels, 12- lead electrocardiogram (ECG), cardiac monitor (e.g., ZOLL® [ZOLL Medical Corp, www.zoll.com]; Tempus Pro™ [Remote Diagnostic Technologies, http://www.rdtltd.com])
- **Better:** laboratory monitoring of potassium levels, cardiac monitor (e.g. ZOLL®, Tempus Pro™)
- **Minimum:** close monitoring of vital signs and circulatory examination
- **Frequency:** every 15 minutes for initial 1–2 hours
- Decrease frequency to every 30 minutes, then hourly if stable or if urine is clearing
- Monitor for premature ventricular contractions (PVCs; skipped beats), bradycardia, decreased peripheral pulse strength, hypotension
- Specific ECG signs: sinus bradycardia (primary sign); peaked T waves, lengthening PR interval (early signs), prolonged QRS interval, PVCs or runs of ventricular tachycardia, conduction block (bundle branch, fascicular)
- If PVCs become more frequent, the patient develops bradycardia, peripheral pulse strength decreases, or potassium levels are >5.5mEq/L or rising, treat urgently for hyperkalemia.
- Insulin and 50% dextrose (D50); calcium gluconate; albuterol (see treatment instructions below).
- Consider teleconsultation or more urgent evacuation to facility with laboratory and ECG monitoring, if possible.
- Use tourniquets to isolate limb(s). (See Tourniquets below.)

Treatments for Cardiac Arrhythmias Due to Hyperkalemia

Treat if potassium level is >5.5mEq/L or there are cardiac arrhythmias (see above). Note that a normal ECG may occur in patients with hyperkalemia.

Goal: Restore normal ECG/prevent fatal cardiac complications.

Treatment for Hyperkalemia

- **Best:** calcium gluconate; insulin + D50; albuterol; sodium polystyrene sulfonate
- **Better:** calcium gluconate; insulin + D50
- **Minimum:** any individual or combination of treatments, as available
- **Calcium gluconate (calcium replacement):** Increases serum calcium to overcome the effect of hyperkalemia on cardiac function.[18] Alternate: may use calcium chloride, which is more irritating when administered via peripheral IV.

  Treatment instructions: Administer 10 mL (10%) calcium gluconate or calcium chloride IV over 2–3 minutes. Onset of effect: immediate. Duration of action: 30–60 minutes.
- **Insulin and glucose:** Insulin is given to lower the serum potassium level by driving it back into the cells; glucose is given to prevent hypoglycemia.[18]

  Treatment instructions: Give 10 units of regular insulin followed immediately by 50mL of D50. Onset of effect: 20 minutes. Duration of action: 4–6 hours.
- **Albuterol:** Lowers serum potassium level by driving it back into the cells; effect is additive with insulin.[19]

  Treatment instructions: Administer 12mL of albuterol sulfate inhalation solution, 0.083% (2.5mg/3mL) in nebulizer. Onset of effect: 30 minutes. Duration of action: 2 hours.
- **Sodium polystyrene sulfonate (Kayexalate®; Concordia Pharmaceuticals,** http://concordiarx.com): Lowers serum potassium level by removing potassium from the gut.[18]

  Treatment instructions: 15–30g suspended in 50–100mL liquid. Oral or rectal. Onset of action: >2 hours. Duration of action: 4–6 hours.
- **Bicarbonate:** Although routinely recommended as mainstay treatment to reduce kidney damage by raising the urine pH and diminishing intratubular pigment cast formation, and uric acid precipitation; to correct metabolic acidosis; and to reduce potassium levels, there is no clear evidence that bicarbonate reduces kidney damage,[20] and the effect of reducing potassium is slow and unsustained.[21]

Sodium polystyrene sulfonate removes potassium from the body. All other treatments temporarily lower potassium by shifting it out of circulation and into the cells. Continue to monitor and repeat treatment when needed.

TOURNIQUETS FOR MANAGEMENT OF CRUSH

Tourniquets may delay the life-threating complications of a reperfusion injury if immediate fluid resuscitation or monitoring is not initially available. Consider tourniquet placement for crush injury before extrication if the length of entrapment exceeds 2 hours and crush injury protocol cannot be initiated immediately.[22–24]

Goal: Delay acute toxicity until after fluid resuscitation and monitoring are available.

- **Best:** Apply two tourniquets side by side and proximal to the injury immediately before extrication

- **Minimum:** Apply two tourniquets side-by-side proximal to the injury immediately after extrication
- Initiate crush injury protocol before loosening tourniquet, and then only if the patient meets criteria for tourniquet conversion or removal given in the TCCC guideline

A limb that is cool, insensate, tensely swollen, and pulseless is likely dead. Patient may develop shock and kidney damage, and may die. Consider fasciotomy. If no improvement, place two tourniquets side by side and proximal to the injury and do not remove. Amputation anticipated.

FASCIOTOMY

Extremity compartment syndrome must be anticipated with crush injury and reperfusion injury.[25–27]

Goal: Decompress muscle, restore blood flow.

- **Best:** Perform fasciotomy (only if there are clinical signs of compartment syndrome). The earliest sign is limb swelling with severe pain with or without passive motion, persisting despite adequate analgesia, followed by paresthesia, pallor, paralysis, poikilothermia, and pulselessness.

Only if qualified medical personnel or teleconsultation (ideally with real-time video capability) available.

  - Then only if wound care available.
  - Regional anesthesia with nerve block or IV sedation required.

- **Minimum:** Cool limb to reduce extremity edema (evaporative or environmental cooling only, do not pack limb in ice or snow because of risk of further tissue damage).
- **Pain management:** Refer to TCCC Guidelines for analgesia on the battlefield.[28]

INFECTION

For infection due to associated wounds and not crush injury itself, follow the Joint Theater Trauma System Infection Control Guidelines: "Prevent Infection in Combat-Related Injuries for Extremity Wounds."[29]

Goal: Prevent infection.

- **Best:** Ertapenem, 1 gm IV/day (1g, 10 ml saline or sterile water)
- **Better:** Cefazolin, 2g IV every 6 to 8 hours; clindamycin (300–450 mg by mouth three times daily or 600 mg IV every 8 hours); or oxifloxacin (400 mg/day; IV or by mouth)
- **Minimum:** Ensure wounds are cleaned and dressed, and hygiene of wounds and patient optimized to the extent possible given environment.

Two appendices accompany this article: Appendix A presents a summary of fluid and equipment planning considerations; Appendix B summarizes monitoring and management considerations relative to time.

APPENDIX A: FLUID AND EQUIPMENT PLANNING CONSIDERATIONS

Best	▪ **Fluids:** IV fluid to provide 1L/h for 24 to 48 hours (depending on evacuation availability) ▪ **Equipment:** ECG, laboratory tests for serum potassium and urine myoglobin, Foley catheter with graduated collection system, tourniquets ▪ **Medications:** hyperkalemia*: calcium gluconate (5 x 10mL vial or Bristojet), insulin: 1 vial Humulin R (500 units; Lilly USA, www.humulin.com), D50 (120mL), albuterol (24 vials), Kayexalate (360g; Concordia Pharmaceuticals, http://concordiarx.com) ▪ **Pain:** refer to Analgesia, Sedation Clinical Practice Guidelines ▪ **Antibiotics:** Ertapenem ▪ **Monitoring:** Continuous monitoring with portable monitor; 15-minute to hourly vital signs, examination, urine output documented on flowsheet **Communications: real-time video telemedicine consultation**
Better	▪ **Fluids:** IV fluid to provide 1L/h for 24 to 48 hours ▪ **Equipment:** Dipstick urine tests to monitor urine, graduated container to monitor urine output, tourniquets ▪ **Medications:** hyperkalemia: calcium gluconate (5 x 10mL vial or Bristojet), insulin: 1 vial Humulin R (500 units), D50 (120mL) ▪ Pain medications ▪ Antibiotics ▪ **Monitoring:** 15-minute to hourly vital signs, examination, urine output documented on flowsheet **Communications: telephone, possibly e-mail telemedicine consultation**
Minimum	▪ Fluids: IV fluid for initial bolus resuscitation (2L), then oral or rectal fluid resuscitation with commercial or improvised electrolyte solution ▪ Equipment: Graduated container to monitor urine output, tourniquets ▪ Medications: hyperkalemia: calcium gluconate (5 x 10mL vial or Bristojet) ▪ Pain medications ▪ Antibiotics ▪ Monitoring: 15-minute to hourly vital signs, examination, urine output documented on flowsheet or other written format **Communications: telemedicine by telephone**

APPENDIX B: CRUSH INJURY, MONITORING AND MANAGEMENT CONSIDERATIONS

			Phase 1 Entrapment	**Phase 2** Extrication	**Phase 3** Immediately Following Extrication	**Phase** 4 Prolonged Field Care
FLUIDS

	Better	Oral electrolyte solution	Continue	Continue	Continue. Goal UOP 100–200mL/h	Continue. Goal UOP 100–200mL/h
	Minimum	Rectal electrolyte solution	Continue	Continue	Continue. Goal UOP 100–200mL/h	Continue. Goal UOP 100–200mL/h
Telemedicine: Consult on management						
Monitoring: 15-minute to hourly vital signs, examination, urine output documented on flowsheet						
VITAL SIGNS						
	Best	Portable monitor with ECG	Record every 15 minutes	Record every 15 minutes	Record every 15 minutes	Record every 1 hour
	Better	Check intermittent vital signs	Every 15 minutes	Every 15 minutes	Every 15 minutes	Record every 1 hour
	Minimum	Monitor pulse and mental status	Every 15 minutes	Every 15 minutes	Every 15 minutes	Record every 1 hour
UOP	Best	Place Foley catheter	N/A	N/A	Record UOP every 1 hour	Record UOP every 2 hours
	Minimum	Capture urine in premade or improvised graduated cylinder				
Urine myoglobinuria	Best	Laboratory monitoring	N/A	N/A	N/A	Every 6 hours
	Better	Assess urine color (red, brown, or even black)				
	Minimum	Dark urine (red, brown, or even black)				
Potassium and cardiac arrhythmia	Best	Laboratory monitoring of potassium levels	N/A	N/A	Check	Every 4-6 hours
		12-lead ECG	N/A	N/A	Check	Every 4-6 hours
	Better	Laboratory monitoring of potassium levels	N/A	N/A	Check	Every 4-6 hours
		3–5 lead ECG	Initiate	Continue	Continue	Continue
	Minimum	Close monitoring of vitals and circulatory examination	Initiate	Continue	Continue	Continue
Treatments for Hyperkalemia (>5.5mEq/L) or Cardiac Arrhythmia						
Calcium gluconate (10%)	Best	10mL IV over 2–3 minutes	N/A	N/A	Monitor; repeat as required	
Insulin (regular) and D50		10 units IV push + 50mL D50	N/A	N/A		
Albuterol (2.5mg/3mL vial)		10mg (4 vials) in nebulizer	N/A	N/A		
Sodium polystyrene sulfonate (Kayexalate)		15–30g suspended in 50–100mL liquid, oral or rectal	N/A	N/A		

			Phase 1 Entrapment	**Phase 2** Extrication	**Phase 3** Immediately Following Extrication	**Phase** 4 Prolonged Field Care
Calcium gluconate 10% Alternate: calcium chloride 10%	Better	10mL IV over 10 minutes				
Insulin (regular) and D50		10 units IV push + 50mL D50	N/A	N/A	Monitor; repeat as required	
Any individual or combination of above, as available	Minimum	See above	N/A	N/A		
Management of Injured Extremity						
Extremity compartment syndrome	Best	Clinical assessment • 6 Ps* • Rigid compartment	---	---	Fasciotomy: only if qualified medical personnel or teleconsultation available	
	Minimum				Cool limb (evaporative or environmental cooling, no ice/snow)	
Tourniquet (for crush management)	Best	If adequate fluids are unavailable, or arrhythmia cannot be managed during entrapment and extrication	If entrapment time >2 hours, consider tourniquet. Place two tourniquets side by side and proximal to the injury	If the patient meets criteria for tourniquet conversion or removal, and fluids are available, initiate crush injury protocol before loosening tourniquet.		
Tourniquet (for irreversible injury)		A limb that is cool, insensate, tensely swollen, and pulseless is likely dead. Patient may develop shock and kidney damage, and may die.				Consider fasciotomy. If no improvement, place two tourniquets side by side and proximal to the injury. Amputation anticipated
Pain						
			Per TCCC	Per TCCC	Per TCCC	Pain/sedation CPG
Infection Control						
Antibiotics	Best	Portable monitor with ECG	Ertapenem, 1g IV/day (1g, 10mL saline or sterile water)			
	Better	Check intermittent vital signs	Cefazolin, 2g IV every 6 to 8 hours; clindamycin (300–450mg by mouth three times daily or 600mg IV every 8 hours); or moxifloxacin (400mg/day; IV or by mouth)			
	Minimum	Monitor pulse and mental status	---	---	Ensure wounds cleaned and dressed, and hygiene of wounds and patient optimized to the extent possible given environment.	

N/A, not applicable; UOP, urine output. *6 Ps: Pain persisting despite adequate analgesia is most important symptom, followed by paresthesia, pallor, paralysis, poikilothermia, pulselessness

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Damage Control Resuscitation

This CPG provides evidence–based guidance to minimize variation in resuscitation practices and improve the care of massively hemorrhaging, severely injured casualties.

SUMMARY OF UPDATES

RAPID UPDATES

***Aug 2023**: Calcium caution statement added.*

Jun 2023

- *Calcium administration changed to 1 gram calcium.*
- *Tranexamic acid (TXA) 2gm bolus is now favored over the traditional 1gm prehospital bolus followed by 1gm infusion over 8 hours. The 2gm TXA bolus should be given as close to the time of injury as possible and not outside of the 3 hours window.*

Jul 2019

- Greater emphasis on the use of Low Titer O Whole Blood (LTOWB) as the optimal strategy to deliver a balanced and maximally hemostatic resuscitation, with platelet functionality, safely.
- Risk factors for massive transfusion (MT), International Normalized Ratio (INR) threshold updated to > 1.5.
- Earlier calcium use recommended. One gram of calcium IV/IO should be given to patients in hemorrhagic shock during or immediately after transfusion of the first unit of blood product and with ongoing resuscitation after every 4 units of blood products. Ideally, ionized calcium should be monitored and calcium should be given for ionized calcium less than 1.2mmol/L.[1-5]
- Blood pressure goals for DCR have been adjusted to a target systolic blood pressure (SBP) goal of 100 mmHg (110mmHg for traumatic brain injury (TBI)).
- Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) updated as a fielded option for the control of non-compressible torso hemorrhage. REBOA continues to be recommended for designated resuscitation teams and NOT intended to be used by the combat medic or corpsman.
- The use of hydroxyethyl starch (Hextend, Hespan) as a resuscitation fluid is NO LONGER RECOMMENDED and has been removed from the guideline.
- The use of recombinant human activated factor VII (rhFVIIa) is no longer recommended.

EXECUTIVE SUMMARY

Hemorrhage is the leading cause of preventable death on the battlefield.[6] Of the 4,596 combat deaths reported in COL Brian Eastridge's 2012 review *Death on the Battlefield*, 976 casualties died with injuries that an expert panel classified as potentially survivable, and the vast majority of these deaths—just over 90%—were secondary to uncontrolled hemorrhage. Subsequent interventions focusing on point of injury hemorrhage control and prehospital Tactical Combat Casualty Care were predictably successful, and particularly when paired with rapid evacuation and prehospital blood resuscitation. In fact, data published in studies by Col Stacy Shackelford et al. showed that blood given in the prehospital setting as soon as possible after injury improved both 24 hour and 30-day survival.[7] In short, in the setting of active hemorrhage, the combination of point-of-injury hemorrhage control (per Tactical Combat Casualty Care guidelines), rapid evacuation, and pre-hospital blood resuscitation saves lives.

BACKGROUND

Damage Control Resuscitation (DCR) is generally accepted as a complementary strategy usually paired with Damage Control Surgery (DCS), which focuses surgical interventions to those which address life- threatening injuries and delays all other surgical care until metabolic and physiologic derangements have been treated.[8] Recognizing that this approach saved lives, DCR was developed to work synergistically with DCS and prioritize non-surgical interventions which may reduce morbidity and mortality from trauma and hemorrhage.[9] The major principle of DCR is to restore homeostasis, prevent or mitigate the development of tissue hypoxia, oxygen debt and burden of shock, as well as coagulopathy.[10,11] This amounts to preventing 'blood failure,' specifically with a goal of restoring blood functionality (improving oxygen delivery and tissue perfusion, reducing acidosis, preventing fibrinolysis, reducing coagulopathy, protecting the endothelium, and reducing platelet dysfunction). This is best accomplished through aggressive hemorrhage control and a blood product-based resuscitation, which restores tissue oxygenation, avoids platelet and coagulation factor dilution, and also replaces lost hemostatic potential. DCR is most effective when resuscitation replaces lost blood with whole blood, whether ideally transfused as units of whole blood (WB), or blood product components transfused in a ratio approximating whole blood (i.e. 1:1:1 ratio of FFP:Plt:RBC). Additional goals of DCR are avoidance or limiting of the use of crystalloids to avoid dilutional coagulopathy, selective use of hypotensive resuscitation (SBP of 100 or SBP of 110, if TBI suspected until surgical control is achieved, correction of coagulopathy and acidosis, maintenance of normothermia, empiric administration of Tranexamic Acid in appropriate patient populations, and expeditious evacuation to damage control and definitive surgical capabilities.

Advanced Trauma Life Support (ATLS) guidelines historically advocated a linear resuscitation strategy beginning with an emphasis on crystalloid infusion, particularly during the pre-hospital phase, followed by the addition of red blood cells (RBCs), and finally plasma. Platelets were delayed until a low platelet count was documented and reserved either for severe thrombocytopenia or thrombocytopenia in the presence of active hemorrhage. As documented in retrospective reports from the civilian trauma literature, this approach resulted in excessive crystalloid use and is associated with a risk of dilutional coagulopathy, abdominal compartment syndrome, multiple organ failure, and death[12]. Although selection bias may have contributed to these findings, it should be noted that the ATLS 10th edition identifies that resuscitation with greater than 1.5L of crystalloid is associated with increased mortality and suggests limiting crystalloid use to no more than one liter during the initial resuscitation. Instead, current ATLS recommendations for bleeding patients are for early administration of blood products, including plasma and platelets, while focusing on rapidly achieving hemorrhage control.[13]

During the conflicts in Iraq and Afghanistan between 2003 and 2012 14% of patients admitted to Role 3 military treatment facilities (e.g., combat support hospitals) received a transfusion of at least one blood product. Of these, 35% received MT. (MT is defined as ≥ 10 units of RBCs and/or WB in 24 hours. The proportion of transfused patients receiving MT reached approximately 50% by 2011 in parallel with increasing injury severity scores, use of blood resuscitation, and decreased use of crystalloid and colloid use.[14] During this period mortality fell as military clinicians became experts in the treatment of very severe multisystem trauma accompanied by massive hemorrhage. Civilian ATLS-based practice gave way to a hemostatic resuscitation approach designed to mimic WB functionality.

There is now strong retrospective evidence in both civilian and military trauma populations that patients requiring MT benefit from a higher ratio of plasma and platelets to red cells (e.g., 1 unit plasma: 1 unit platelets: 1 unit RBCs). MT at a 1:1:1 ratio is associated with improved survival.[9, 15-18] Recently, prospective randomized data from the Pragmatic Randomized Optimal Platelet and Plasma Ratios (PROPPR) trial revealed that mortality at 3 hours after injury due to exsanguination was lower in patients resuscitated with a 1:1:1 ratio compared to 1:1:2.[13] These were important findings given that the differences between resuscitation strategies were small—and probably best characterized by an early vs. late platelet approach. There was no difference in overall mortality at 24 hours or 30 days, likely due to the confounding effect of head injury. Balanced resuscitation was not associated with increased complication rates.[19,20]

Although physicians continue to debate the lessons of the PROPPR trial and the relative benefits of specific blood component ratios, the practice of giving large amounts of crystalloid or RBCs alone during the initial resuscitation is no longer standard practice. As stated above, in combat casualties with bleeding, EARLY blood product resuscitation (ideally within 36 minutes of injury) provides the lowest early and late mortality rates.[2] Available data on balanced resuscitation comes from component-based resuscitation. We know that any blood product combination represents an advantage over salt-based crystalloids for the bleeding casualty. However, LTOWB represents the best way to deliver a functional resuscitation early, clinically as well as logistically.

BLOOD PRODUCTS FOR DCR

WHOLE BLOOD

Whole blood delivers all the components of blood in the same ratio in which they were lost; WB is independently associated with improved survival.[21-23] In deployed environments, the logistical challenges of maintaining a supply of blood components have led to the use of WB collected onsite from “walking blood banks,” specially to provide platelets for hemostatic resuscitation. Depending on where the blood products have been collected, some of the whole blood products in the deployed setting (platelets or WB) are not prospectively tested for Transfusion-Transmitted Diseases (TTDs). Rapid TTD test kit use is encouraged to screen for HIV, Hepatitis B and C, and malaria or other diseases for which kits are available. Recipients of these blood products must be tested at 3-, 6- and 12-months post- transfusion to monitor for disease transmission.

Type-Specific Whole Blood (TSWB), often referred to as Fresh Whole Blood (FWB), is collected from donors in the deployed setting and must be an ABO match with the recipient. The availability of TSWB may be limited due the constrained pool of donors who must be tested for TTDs and blood group compatibility with recipients. In addition, the chaotic conditions of mass casualty scenarios complicate the matching of blood types between donors and recipients, increasing the risk of clerical errors causing hemolytic transfusion reactions.

In order to improve the availability and safety of WB, low anti-A and anti-B titer (<256 by tube method, though the definition of ‘low titer’ can vary by medical agency or facility) group O blood has been identified

as a practical, effective universal blood product for resuscitation of exsanguinating hemorrhage.[24,25] Like all blood donors, "O low titer" donors should be tested for TTDs and undergo confirmatory typing and an antibody screen (type and screen) in addition to testing for anti-A and anti-B antibodies. LTOWB can be collected from pre-screened walking blood banks in the deployed setting or collected in Armed Services Blood Program donor centers and stored refrigerated for 21 days in CPD or 35 days in CPDA-1.[26] It is important to note that LTOWB has been used safely in the military setting since WW1, with hundreds of thousands of units transfused and only one recorded hemolytic reaction, due to a clerical error.[27]

In 2014 the U.S. Army Rangers developed and instituted the Ranger O Low titer blood (ROLO) program. Low Titer Rangers were identified as a screened donor pool serving as an immediate WBB capability (approximately 2/3 of the group O Ranger population is naturally low titer, generally accepted as having anti-A and anti-B levels less than 1:256 concentration). Every Ranger is trained in how to set up and administer a Fresh Whole Blood buddy transfusion. This program represents a success story of leadership and since 2015 every Ranger task force has deployed with a functional ROLO program. This model is currently being broadened to other prehospital communities.

Available data suggest that Cold-Stored WB (CWB) will provide robust platelet hemostatic function during the first 2 weeks of storage. When using anticoagulants and preservatives such as CPD and CPD-A, function is moderately reduced during the remaining shelf life (21 days for Citrate Phosphate Dextrose (CPD) WB and 35 days for Citrate Phosphate Dextrose Adenine (CPDA-1) WB), but it should be noted that some platelet function remains and that WB plasma hemostatic function is comparable to that of liquid plasma. Throughout its shelf life, CWB remains a relatively hemostatic product compared to RBCs and plasma alone[28-30] Patients receiving MT with CWB stored for more than 2 weeks may require additional support with platelet transfusions or FWB (consider a ratio of 3:1 of CWB: FWB as available). Similarly, CWB that has been leukoreduced with a filter that does not spare platelets and that contains fewer or effectively no platelets require supplementation with platelet or FWB transfusion.[31] Cold-stored LTOWB and TSWB have been used successfully and safely to treat trauma and other causes of massive hemorrhage, such as obstetric emergencies and bleeding in cardiac surgery, in leading U.S. civilian hospitals.[30,32-40]

WB is standard practice for resuscitation of combat casualties. For guidance regarding use of FWB, see the Joint Trauma System (JTS) CPG entitled *Fresh Whole Blood Transfusion*.[41]

RED BLOOD CELLS

RBC units may be stored for up to 42 days under refrigeration when stored in additive solution (e.g., AS-5) or 35 days if stored in CPDA1. In addition, "frozen" RBCs (stored frozen with glycerol cryoprotectant for up to 10 years at <-65°C, then thawed and rinsed in an automated process prior to transfusion) are used interchangeably and successfully with standard RBC units when needed, although these units require at least an hour and a half and specialized equipment to prepare. Transfusion of thawed fRBC units without removal of glycerol is absolutely contraindicated and is lethal to the recipient. Thawed and deglycerolized RBCs can be stored for 14 days with refrigeration. For guidance regarding use of fRBCs see the JTS CPG entitled *Frozen and Deglycerolized Red Blood Cells*.[42]

PLASMA

Plasma can be stored frozen and then thawed on-demand (FFP), or pre-thawed and stored refrigerated for up to 5 days (so-called "thawed plasma"). The delay in treatment imposed by slow thawing of FFP (up to 30 minutes or more) has necessitated the widespread maintenance of thawed plasma inventories for immediate, emergency use. This typically results in significant waste due to the 5-day post-thaw shelf life. Plasma can also be supplied as "liquid" (never frozen) plasma and stored for 26 days in CPD anticoagulant

solution, or 40 days in CPDA-1. Available data suggest that "thawed" and "liquid" plasma may be functionally interchangeable in most trauma patients. Note that no randomized trials have compared these products and the data regarding the hemostatic capacity of liquid plasma stored beyond 28 days are very limited.[42,43] Although group AB plasma is classically considered the universal donor, it is now widely recognized that A plasma can, in fact, be considered universal since group A individuals do not generally make high titer anti-B antibodies and B red cells express the B antigen at low density, thus making them much less susceptible to hemolysis than A red cells.

Freeze-Dried Plasma (FDP) was used by U.S. Forces during World War II and has been in use by the French military since the 1940s. French military FDP is available to U.S. Special Operations Forces under an Emergency Use Authorization from the Food and Drug Administration (FDA).[24] FDP is considered functionally interchangeable with other plasma products for trauma resuscitation. FDP or Spray-Dried Plasma (SDP) may become more broadly available to U.S. Forces in the near future.[44-45]

PLATELETS

In contrast to red cells and plasma, platelets collected in theater by apheresis traditionally have been stored at room temperature (20-24°C), under constant agitation, for a maximum of 5 days with an extension to 7 days total if shipped to another facility. These storage conditions are optimized to extend in vivo platelet circulation, but not hemostatic function, safety, or availability.[46] Platelets are vital for hemostasis and their early use in a balanced transfusion strategy is associated with increased survival in trauma.[16,19,47,48] Platelets stored under refrigeration (1-6°C), or "Cold-Stored Platelets" (CSP), maintained without agitation for up to 3 days in plasma, have long been approved by the FDA for treatment of bleeding patients. Refrigerated storage better preserves platelet hemostatic function and clearly reduces the risk of bacterial growth, the major hazard of transfusing room temperature-stored platelets.[49,50] CSP have been proven effective in clinical trials and used successfully in combat trauma patients in the U.S. Central Command area of operations.[53] Cold-stored platelets in platelet additive solution (CSP-PAS) or plasma retain function for at least 15 days and are compatible with blood warmers and rapid infusers.[51] CSP can be collected in theater and used interchangeably with other platelet products.[52]

Fibrinogen concentrate has not been studied adequately in trauma patients either, but several factors suggest that it may be helpful. These include: 1) fibrinogen is the fundamental substrate of clot formation; 2) fibrinogen is rapidly consumed in trauma; and 3) cryoprecipitate, a less purified source of fibrinogen, has been shown to be an essential component of MT protocols for mitigating the dilutional coagulopathy caused by red cell additive solution and anticoagulant.[17,53-56]

Prothrombin Complex Concentrates (PCCs) are only indicated for patients requiring urgent warfarin reversal and have not been adequately studied in a broad trauma population. PCCs could be considered if: 1) the patient is anticoagulated; or 2) there is clear evidence of delayed initiation of clot formation refractory to platelets, fibrinogen, or cryoprecipitate and TXA (e.g., prolonged thrombelastography rapid time [TEG-R] or rotational thromboelastometry clotting time [ROTEM CT]). PCCs should not be routinely used in trauma outside the context of a clinical trial as they may cause harm due to excessive thrombogenicity.[57]

HEMOSTATIC ADJUNCTS FOR DCR

MECHANICAL HEMORRHAGE CONTROL

In addition to blood replacement, DCR strategies also focus on limiting blood loss with hemorrhage control devices and adjunctive pharmaceutical therapies. Availability and usefulness ofinterventions are determined by the type of injury and location of bleeding. Effective tourniquets (e.g., Combat Application

Tourniquet, Special Operations Forces Tactical Tourniquet) have been developed for extremity injury and may be responsible for saving more wounded service members in Iraq and Afghanistan than any other single medical intervention. Junctional (axillary, neck, and groin) hemorrhage, previously a nearly intractable problem, can now be treated with approved junctional tourniquets (e.g., Combat Ready Clamp, SAM® Junctional Tourniquet, Junctional Emergency Treatment Tool) and the XSTAT™ device, which injects absorbent sponges into deep wounds to tamponade bleeding.[58-60] Superficial wounds are amenable to novel and effective hemostatic dressings (e.g., Combat Gauze or Celox/Celox Rapid gauze).

Truncal internal hemorrhage is non-compressible and is the subject of intensive research. Resuscitative Endovascular Occlusion of the Aorta (REBOA) has emerged as a technique for truncal hemorrhage control. The newest device available does not require fluoroscopic guidance and has become widely available; in expert hands on teams with appropriate training, REBOA may improve survival from non- compressible truncal hemorrhage. There is no 24-hour outcome data on the use of REBOA in the combat environment. Teams that use this technique should be submitting clinical data to the JTS in order to better understand this capability and how it effects outcomes from hemorrhage. The ideal application of REBOA in the combat environment is evolving, but the technique, when used appropriately, has the potential to significantly improve outcomes from non-compressible truncal hemorrhage. Currently, REBOA use is supported for austere surgical teams, and teams that have an immediate surgical capability are using REBOA. See the JTS *REBOA for Hemorrhagic Shock* CPG. [61-67]

PHARMACOLOGIC ADJUNCTS

Hemostatic pharmaceutical adjuncts to limit blood loss are another subject of considerable investigation.

Tranexamic acid (TXA) is the only therapy in this class that has been found to reduce mortality in a large Randomized Controlled Trial (RCT). Strong evidence demonstrates a significant improvement in survival following the early use of TXA, but only when given within 3 hours of injury.[68,69] Significant trauma-- in particular, penetrating trauma with hemorrhage--has been associated with coagulopathy, in part secondary to the activation of fibrinolysis.[1,70] Such hyperfibrinolysis occurs in the most severely injured patients (approximately 4% of trauma patients in major civilian U.S. trauma centers) and portends poor outcomes.[9,71] Anti-fibrinolytic agents, including TXA, have been used to decrease bleeding and to reduce the need for blood transfusions in coronary artery bypass grafting, orthotopic liver transplantation, hip and knee arthroplasty, obstetrics, and other surgical settings. The safety and efficacy of using TXA to treat trauma patients was evaluated in a large randomized, placebo-controlled clinical trial *The Clinical Randomization of an Antifibrinolytic in Significant Hemorrhage (CRASH-2).*[72] In this trial, 20,211 adult trauma patients in 274 hospitals in 40 countries with, or at risk of, significant bleeding (HR>110, SBP<90, clinical judgment) were randomized to either TXA or placebo. The authors reported that TXA use resulted in a statistically significant reduction in the relative risk of all-cause mortality of 9% (14.5% vs.

%, RR 0.91, CI 0.85-0.97; p = 0.0035). It was in this group of most severely injured patients thatuse of TXA was associated with the greatest reduction in risk of death.

A registry-based study of combat-injured troops receiving blood in Afghanistan (January 2009 - December 2010) demonstrated a decreased mortality with TXA use in this population. The TXA group was more severely injured (ISS: 25.2±16.6 vs. 22.5±18.5; p<0.001), required more blood (11.8±12.1 vs. 9.8±13.1 pRBC units; p<0.001), had a lower Glasgow Coma Score (7.3±5.5 vs. 10.5±5.5; p<0.001) and initial systolic blood pressure (112±29.1 vs. 122.5±30.3 mmHg), but also had a lower unadjusted mortality than the no-TXA group (17.4% vs. 23.9%; p=0.028). In the massive transfusion cohort (N=321; 24-hour transfusion: 21.9±14.7 pRBC; 19.1±13.3 FFP and 3.5±3.2 apheresis platelet units), mortality was also lower in the TXA group compared to the no-TXA group (14.4% vs. 28.1%; p=0.004). In a multivariate regression model, TXA use in the massive transfusion cohort was independently associated with survival (odds ratio: 7.28; 95% confidence interval:

3.02-17.32). A subsequent larger retrospective analysis of TXA use outcomes in military casualties documented an increased rate of venous thromboembolism in patients receiving TXA.[73] Estimates of TXA effects on mortality suggested that an adequately powered study would likely observe an effect size in line with CRASH-2 findings.

This survival benefit associated with TXA supports its use in conjunction with damage control resuscitation following combat injury. This association is most prominent in those requiring massive transfusion.[14,74] In casualties at high risk of hemorrhagic shock, ***TXA reduces mortality IF GIVEN WITHIN THREE (3) HOURS of injury***, optimal use of TXA requires that it be given as soon as possible when indicated rather than suggesting that TXA administration any time within 3 hours after injury is acceptable.[75,76] TXA given empirically greater than 3 hours post-injury increases the risk of mortality. For eligible casualties, 2 grams of TXA should be administered IV or IO. (See next section *Recognition of Patients Requiring DCR* to determine eligible casualties.) TXA is ideally administered in 100 ml of normal saline over 10 minutes, but faster administration in more concentrated form can be considered. Administration of undiluted TXA by slow IV push (given over 10 minutes) is acceptable if supplies or tactical situation prevents 100mL IV infusion.[77] It should be noted that rapid infusion of TXA has been infrequently associated with transient hypotension. Although Lactated Ringer's (LR) solution is compatible with TXA, its use should be avoided in this setting since the mixing of calcium containing LR with blood products in chaotic resuscitation settings may cause clotting of blood products and thromboembolic phenomena. Normal saline and PlasmaLyte A are the only crystalloid solutions compatible with blood products.

CAUTION: Do not mix medications and blood products in the same IV line. Use a separate line or flush well between giving medications and blood products.

Hypocalcemia is a problem in most actively bleeding trauma patients on presentation, and administration of even one unit of citrated blood product can further lower ionized calcium to levels approaching critical values (<0.9mmol/l). One gram of calcium IV/IO should be given to patients in hemorrhagic shock during or immediately after transfusion of the first unit of blood product and with ongoing resuscitation after every 4 units of blood products. At a minimum, one gram of calcium should be administered after no more than 4 units of blood product have been infused to avoid citrate toxicity. Ideally, ionized calcium should be monitored and calcium should be given for ionized calcium less than 1.2mmol/L. This should be done at the first level of care capable of monitoring these patients, typically a Role 2 equivalent or above. Appropriate calcium solutions should otherwise be administered per protocol for signs and symptoms of hypocalcemia (e.g., prolonged QTc, ventricular arrhythmias, decreased cardiac output/cardiovascular collapse, coagulopathy, tetany, laryngospasm, seizures, and paresthesia).

CAUTION: Calcium gluconate is safer for peripheral use. Calcium chloride may cause severe skin necrosis if extravasation occurs through a partially dislodged IV or IO catheter. The risk of bone necrosis with IO injection of calcium chloride is not known. When using peripheral IV or IO access, use extreme caution to ensure the device is in good intravascular position and no extravasation occurs.

Note that hypomagnesemia is also common in trauma patients and is worsened by citrate- containing blood products. Hypomagnesemia may contribute to increased cardiac irritability and risk of fatal arrhythmias. Consideration should be given to replacing magnesium in the setting of severe hypocalcemia and massive transfusion.[4,78-80]

The use of rFVIIa is no longer recommended in most trauma patients since it has not been shown to reduce mortality and may increase risk of adverse events.[81-85]

MANAGEMENT PRINCIPLES FOR DCR

RECOGNITION OF PATIENTS REQUIRING DCR

Patients receiving uncross matched Type O blood in the Emergency Department (ED) or resuscitation area and later receiving cumulative transfusions of 10 or more RBC units in the initial 24 hours post- injury (MT) are widely recognized as being at increased risk of morbidity and mortality due to exsanguination. Ideally, these patients should be rapidly identified and hemostasis established at the earliest level of care possible in order to prevent or mitigate shock and coagulopathy. Due to diagnostic challenges, particularly in the case of truncal hemorrhage, anticipating the transfusion needs of these patients requires experience and the coordination of extensive resources, including development of MT protocols.

Robust pre-hospital data are lacking, but a number of factors predict the need for MT support in trauma.[86] In a patient with serious injuries, the presence of 3 of the 4 features below indicates a 70% predicted risk of MT and 85% risk if all 4 are present:

- Systolic blood pressure < 100 mm Hg
- Heart rate > 100 bpm
- Hematocrit < 32%
- pH < 7.25

Other risk factors associated with MT or at least need for aggressive resuscitation.[86-90]

- Injury pattern (above-the-knee traumatic leg amputation especially if pelvic injury is present, multi-amputation, clinically obvious penetrating injury to chest or abdomen)
- >2 regions positive on FAST scan
- Lactate concentration on admission >2.5
- Admission INR ≥ 1.5
- BD > 6 mEq/L

Recognition of clinical patterns associated with the need for MT is essential for effective triage. These include uncontrolled truncal or junctional bleeding, uncontrolled major bleeding secondary to large soft tissue injuries, proximal, bilateral, or multiple amputations, a mangled extremity, clinical signs of coagulopathy (e.g., paucity of clots or petechial bleeding), or severe hypothermia. It is critical to communicate with the blood bank at the medical treatment facility when a potential MT patient has been identified. Blood banks within theater have developed procedures for providing blood products in the appropriate proportion to support resuscitative efforts. Upon arrival to the ED, laboratory evaluation such as viscoelastic testing (TEG or ROTEM) may also facilitate early identification of patients who will require MT, although this technology is not widely available in the deployed setting, particularly at Role 2 facilities.[91,92] It should be noted that many point-of-care coagulation tests that measure Prothrombin Time/International Normalized Ratio (PT/INR) have linear ranges only between INR 2.0-3.0 and are unreliable in clinical conditions characterized by loss of fibrinogen. These devices should not be relied upon to evaluate the coagulation function in trauma patients.[93,94]

POINT OF INJURY, EN-ROUTE, & REMOTE DCR

For detailed recommendations on prolonged field care (PFC) damage control resuscitation, see the *JTS Damage Control Resuscitation for PFC CPG, 01 Oct 2018*.

OPTIMIZATION OF FLUIDS

Volume resuscitation, particularly crystalloid and colloid, should be used sparingly in the pre-hospital setting, given the potential for harm and the limited resources; blood products are preferred for hemorrhagic shock resuscitation.[9,95] WB (Group O low titer preferred) or blood components given ideally at a 1:1:1 (plasma, platelets, RBC) ratio should be transfused when shock is present or expected. Blood products should ideally be warmed with approved in-line blood heaters with the goal of transfusing products warmed to 37°C.

Casualties at low risk of developing shock should NOT receive IV fluids or adjunctive medications.

Hypertonic Saline does NOT improve mortality in hemorrhagic shock and should only be used for patients with TBI and evidence/suspicion of raised Intracranial Pressure (ICP).[96,97] Vasopressors are NOT recommended for the treatment of hemorrhagic shock.

A key element of fluid optimization is careful documentation of all fluids, interventions, and medications given in the pre-hospital phase.

ADJUNCTIVE THERAPIES IN PFC

Compressive / hemostatic dressings and devices

Prevent further hemorrhage with direct pressure, topical hemostatic dressings, and/or tourniquets, if possible, to minimize the risk of shock. REBOA can be highly effective if rapidly implemented by skilled and designated teams.

Prevention of acidosis and hypothermia

Metabolic acidosis resulting from acute trauma is a consequence of inadequate tissue perfusion leading to lactic acid production and is best addressed with resuscitation with WB or equal ratio components. Crystalloid resuscitation will contribute to the acidosis and should be avoided. Hypothermia is multifactorial and strategies should address as many causes as are identified, including cold exposure, cold resuscitation fluids, significant blood loss, and shock. Hypoperfusion contributes to development of hypothermia due to decreased heat production. Prior to arrival at the military treatment facility, heated fluids, fluid blankets, and ventilators may not be available, but wounds should be covered, “space blankets” (e.g., HPMK) used to cover the casualty, and shock avoided or treated. See JTS Hypothermia Prevention CPG for additional information.[98] In patients with isolated extremity injuries treated with tourniquets, the extremity distal to the tourniquet should be left exposed and cooled relative to the patient’s core in order to increase the likelihood of preserving the ischemic limb’s viability.[99]

Expeditious delivery to definitive surgical control

Casualties may require care as described and emergency procedures for life-threatening conditions in the pre-hospital setting; however, these should be balanced against the need to expeditiously deliver the patient to definitive care. DCS at Role 2 forward surgical units should focus only on control of hemorrhage and prevention of ongoing contamination. Only absolutely necessary procedures should be performed. In

general, every effort should be made to deliver the critically injured casualty to the highest available level of care as rapidly as possible.

DCR AT MEDICAL TREATMENT FACILITIES

Although principles remain the same, DCR in medical facilities differs in that there are more resources available, including access to operative surgical control. Also, some therapies such as TXA may have already been given in the pre-hospital phase. Resuscitation to physiologic endpoints such as lactate and base deficit should be considered since tissue hypoxia and oxygen debt are known drivers of coagulopathy. Reversal of tissue hypoxia should thus be a central tenet of hospital-based resuscitation. Specifically:

OPTIMIZATION OF FLUIDS

Volume resuscitation with crystalloids should NOT be first line of care in MTFs due to the potential for harm. Crystalloid fluids should be reserved for specific clinical uses, such as carrier fluid for intravenous medication or other non-resuscitative uses. The order of priority for fluid administration should be:

- Fully TTD tested (performed in FDA registered testing facility/FDA approved) whole blood
- Blood components at a 1:1:1:1 ratio (plasma:platelets:RBC:CRYO)
  Note that apheresis platelets may be collected in theater and therefore are not FDA approved and fully tested prior to transfusion.
- Whole blood from a recently tested donor *(**NOTE:** this option is only acceptable in the hospital for emergency indications when full component therapy is not available)*
- RBCs plus plasma=1:1 ratio
- Plasma with or without RBCs
- RBCs alone

BLOOD PRODUCT TRANSFUSION

Cryoprecipitate is available in hospital settings and should be added to the component mix to create a 1:1:1:1 ratio of products in order to adequately supply fibrinogen and other clotting factors (Factors VIII, XIII, and vWF).

When operationally necessary due to component shortages, WB from walking blood banks can be life-saving. For additional information, refer to the *JTS Whole Blood Transfusion CPG*.[41]

Continual reassessment of the casualty status is needed during and between transfusions. As the patient stabilizes, component ratios should be replaced by 'goal-directed' therapy guided by laboratory evaluation, including CBC, blood gases, calcium levels, PT/INR, Activated Partial Thromboplastin Time (aPTT), and viscoelastic testing (ROTEM® or TEG) if available.

ADJUNCTIVE THERAPIES AT MTF'S

Hypotensive resuscitation

As in the pre-hospital period, resuscitation of casualties without CNS injury prior to definitive surgical control should maintain a lower target SBP (100 mmHg, range 90-110mmHg) to reduce hemorrhage by minimizing intravascular hydrostatic pressure. Hypotensive resuscitation should not be utilized for patients with

isolated CNS injury because of associated adverse outcomes in this population (goal SBP >110mmHg). For additional information, see the *JTS Neurosurgery and Severe Head Injury CPG*.[97]

Compressive / hemostatic dressings and devices

Until definitive surgical control is established, prevent further hemorrhage with direct pressure, topical or truncal hemostatic dressings, and/or tourniquets or REBOA to avoid the development of shock. In extremis, procedures such as resuscitative thoracotomy are indicated. Use of these devices should occur as rapidly as hemorrhage is identified and should not unnecessarily delay transport to the operating room.

Prevention or correction of hyperfibrinolysis

TXA should be given to casualties at risk of hemorrhagic shock who have not already received a dose during the pre-hospital phase. THE CASUALTY SHOULD ONLY RECEIVE INITIAL TXA IF ADMINISTERED WITHIN THREE (3) HOURS OF INJURY. When given > 3 hours post-injury, TXA increases the risk of mortality. The mortality data were not analyzed in patients with hyperfibrinolysis documented by viscoelastic testing (ROTEM® or TEG). However, documented hyperfibrinolysis in the setting of ongoing hemorrhage should be treated according to clinical judgment. For eligible casualties (see section above titled Recognition of Patients Requiring DCR), 2 grams of TXA should be administered IV or IO. TXA is ideally administered in 100 ml of normal saline over 10 minutes, but faster administration in more concentrated form can be considered. It should be noted that rapid infusion of TXA has been infrequently associated with transient hypotension.

Prevention of acidosis and hypothermia

Hypothermia is multifactorial and strategies should address as many causes as are identified, including cold exposure, cold resuscitation fluids, significant blood loss, and shock. Hypothermia occurs even when ambient temperatures are elevated and medical personnel are uncomfortably warm, due to blood loss and hypoperfusion. Treatment should include urgent, active re-warming with all available means including heated fluids, heated blankets, ventilators, warm environments, and rapid surgical care to minimize blood and heat loss.

Expeditious delivery to definitive surgical control

As with casualties in the pre-hospital setting, pre-surgical care should be balanced against the need to expeditiously deliver the patient to the operating room.

CONCLUSION

The DCR approach to the initial management of a critically injured casualty requires a significant expenditure of resources and the coordination of a diverse group of health care providers. This is frequently performed in a clinical scenario of multiple casualties and limited resources. It is incumbent upon the clinical leaders at each level of care to be fully versed on available resources and to employ them judiciously and appropriately. Patients requiring MT should be resuscitated using DCR principles and should undergo early DCS.

PERFORMANCE IMPROVEMENT MONITORING

POPULATION OF INTEREST

1. All patients who receive blood product transfusion within 3 hours of injury

2. All patients with severe traumatic injury (ISS ≥16 and ≥ 2 body regions injured with AIS severity ≥ 2 AND SBP < 100 OR HR > 100 OR hematocrit < 32% OR pH <7.25 within 3 hours of injury)
3. Massive transfusion includes all patients who received 10 or more units of RBC + WB within first 24 hours.

INTENT (EXPECTED OUTCOMES)

1. All patients in the population of interest receive TXA within 3 hours after injury.
2. All patients in the population of interest who receive 1 or more units of blood product also receive calcium.
3. All MT patients receive transfusion of plasma:RBC in a ratio between 0.5:1 to 1:1.5.
4. All MT patients receive platelet or WB transfusion.
5. All MT patients receive cryoprecipitate or WB.
6. For the population of interest, the first resuscitation fluid given after injury is a blood product, ideally cold-stored LTOWB.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who receive TXA within 3 hours after injury (or documented ROTEM indicating no fibrinolysis).
2. Number and percentage of patients in the population of interest receiving 1 or more units of blood product who also receive calcium.
3. Number and percentage of MT patients who receive plasma:RBC in a ratio between 0.5:1 to 1:1.5. (calculate ratio for first 24 hours).
4. Number and percentage of MT patients who receive platelet or WB transfusion.
5. Number and percentage of MT patients who receive cryoprecipitate or WB.
6. Number and percentage of patients in population of interest who received a blood product as the first resuscitation fluid.
7. Number and percentage of patients in population of interest who received cold-stored LTOWB as the first resuscitation fluid.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)
- Theater Medical Data Store

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

APPENDIX A: EXAMPLE OF A MASSIVE TRANSFUSION PROCEDURE AT USCENTCOM LEVEL III FACILITY

CONSIDERATIONS FOR USE WITH MASSIVE TRANSFUSION (MT)

- A flexible procedure for use in the Emergency Department (ED), Operating Room (OR) and Intensive Care Unit (ICU) which can be initiated or ceased by the site-specific provider as dictated by the patient's needs when in that specific venue. It consists of batches as defined below, which vary in composition, but are directed toward approximating a 1:1:1:1 ratio of FFP, platelets, RBC, and cryoprecipitate (CRYO). Note: one unit of apheresis platelets is approximately the equivalent of 6 units random donor platelets, therefore 1u apheresis platelets should be given for every 6 units of RBC to approximate 1:1:1 resuscitation. Crystalloid infusion should be minimized and limited to use as carrier fluid. Hextend® should not be used.
- Note that the MT protocol described below is designed for use with blood components and is designed to provide the functionality of WB. If using WB for MT, the considerations that can be applied from the protocol below include early use of TXA and calcium. Also, if using primarily CWB that has been stored for more than 2 weeks, consider supplementing with additional platelets, either from FWB (consider a ratio of 3:1 of CWB: FWB as available) or from apheresis platelets (consider adding 1 unit of platelets after every 6-10 CWB units if clinically indicated).

Initiate MT procedure if patient has received 4u RBC/4u FFP emergency release blood products.

- Pack One: 6u RBC, 6u FFP, 1u apheresis platelets, 1-2 5-unit bags of cryo. Give TXA empirically if within 3 hours of injury: Infuse 2 grams of TXA in 100 ml of 0.9% NS over 10 minutes intravenously in a separate IV line from any containing blood and blood products. (A more concentrated or rapid injection can be considered but rapid TXA infusion has been infrequently reported to cause transient hypotension.) Give one gram calcium during or immediately after first blood product administered and another gram after every four units of blood product.
- Pack Two: 6u RBC, 6u FFP, 1u apheresis platelets, 1-2 5-unit bags of cryo. Continue to monitor ionized calcium or give 1gm calcium after every 4 blood products.
- Pack Three and beyond: identical to Pack Two

Definitions

Emergency Release: Uncross matched 4u RBC (generally O+ but may be O- for females under the age of 50 if available) and 4u AB or A plasma (NOTE: A plasma is not "universal" but risk of hemolysis in B or AB patients is very low and its use in massive transfusion patients when supplies of AB FFP are limited or absent may improve survival and help preserve resources. A plasma is commonly used as emergency release plasma throughout the United States.)

APPENDIX B: PEDIATRIC CONSIDERATIONS

There are no prospective studies of transfusion resuscitation in pediatric trauma. Most major children's centers extrapolate from adult literature and are using similar damage control resuscitation strategies in major hemorrhage. There are currently no data determining which patients may benefit from these strategies. See Appendix A for a suggested MT Protocol.

For children under a weight of 30 Kilograms (KG), transfusions of RBC units, FFP, or apheresis platelets should be given in "units" of 10-15 ml/kg. One unit of cryoprecipitate is typically administered for every 10 kg of body weight. Blood volume in children can be estimated at between 60-80ml/kg. Bear in mind that a "trauma pack" containing 6 U RBCs + 6 U FFP + 1 U apheresis platelets will deliver between 3000- 4000ml of intravascular volume. A child of 30kg may have a TOTAL blood volume of 1800-2400ml. Over- resuscitation contributes to morbidity and mortality. It may be more convenient and safer to resuscitate children with WB since this product delivers full oxygen delivery and hemostatic functionality and may support more accurate volume dosing. For example, a typical unit of whole blood contains about 500- 600ml (depending on bag type and volume: 450 or 500ml blood volume plus anticoagulant). For a severely injured, shocked child, a quarter to a half of a WB unit may provide adequate initial resuscitation, which can then be further titrated.

Pediatric approved Intraosseous (IO) devices can be used for transfusion if required. Note that sternal IOs designed for adults may pierce a child's sternum and deliver fluids or blood products into the mediastinum.

A MT in pediatrics has been defined as ≥40ml/kg of blood products in 24 hours.[1] The circulating blood volume in children is approximately 60-80 ml/kg. Children are at high risk of developing hypocalcemia, hypomagnesemia, metabolic acidosis, hypoglycemia, hypothermia, and hyperkalemia during MTs.

Therefore, frequent monitoring and correction of acid/base status, electrolytes, and core temperature is essential during the resuscitation of pediatric casualties. An approved blood warmer and other transdermal temperature management system devices are recommended for the prevention and treatment of hypothermia.

Although there are limited retrospective data demonstrating the benefit of TXA in pediatric trauma,[2] there are studies of TXA use in pediatric cardiac, orthopedic, and cranial surgeries showing overall safety and decreased transfusion requirements.[3-6] There is no prospectively validated dosing available for pediatric trauma but loading doses of 10-100 mg/kg IV followed by 5-10 mg/kg/hour infusion doses are commonly used in elective surgery. The UK Royal College of Pediatrics and Child Health has recommended a loading dose of 15mg/kg (up to 1 gm) followed by 2mg/kg/hr over 8 hours (or up to 1gm over 8 hours). This regimen reflects standard adult dosing in trauma.[7]

Viscoelastic clot testing (e.g., TEG or ROTEM®) can be utilized to direct transfusion requirements as in adults utilizing the same thresholds discussed in this CPG.[8] Viscoelastic testing should not be used to withhold TXA during initial resuscitation of bleeding trauma patients.[9]

Prolonged CPR > 20-30 min is generally futile in children who have cardiac arrest with trauma related injuries. Children with traumatic injuries with in-hospital cardiac arrest have a very high mortality after 20-30 min of cardiac arrest.[10]

APPENDIX C: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command-required, unapproved uses. Some command-requested, unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard practice." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Damage Control Resuscitation (DCR) in Prolonged Field Care (PFC)

The purpose of this guideline is to improve implementation of DCR in the Role 1 PFC environment.

RAPID UPDATES

01 Sep 2023*: SAVeO2 oxygen parameters*

Jun 2023

- *Calcium administration changed to 1 gram calcium*
- *Tranexamic acid (TXA) 2gm bolus is now favored over the traditional 1gm prehospital bolus followed by 1gm infusion over 8 hours. The 2gm TXA bolus should be given as close to the time of injury as possible and not outside of the 3 hours window.*

INTRODUCTION

Early recognition and intervention for life-threatening hemorrhage are essential for survival. The immediate priorities are to control life-threatening hemorrhage and maintain vital organ perfusion with rapid blood transfusion.[1]

Experience with fresh whole blood (FWB) resuscitation by military surgical teams deployed in US Central Command [2–4] led to a revolutionary change in resuscitation practices, termed damage control resuscitation (DCR).[5] As DCR became the accepted standard in military and civilian trauma practice, the realization that the majority of potentially preventable battlefield deaths occurred prehospital and were attributed to hemorrhage[6] launched a campaign to bring advanced resuscitation capabilities closer to the point of injury.[7,8]

Efforts to prevent death from hemorrhage begin with external hemorrhage control, followed by transfusion of whole blood (WB) or reconstituted WB with components in a 1:1:1 unit ratio when possible.[9] DCR also limits the use of crystalloids to avoid dilutional coagulopathy and incorporates other adjunctive measures to mitigate hemorrhagic shock and acute traumatic coagulopathy, including:

- Early use of tranexamic acid (TXA)[10]
- Calcium repletion in patients at risk of hypocalcemia
- Prevention of acidosis and hypothermia
- Expeditious delivery to a damage control surgical capability

The purpose of this prolonged field care (PFC) guideline is to improve implementation of DCR in the Role 1 [11] PFC environment by augmenting and consolidating the Tactical Combat Casualty Care (TCCC) and Joint Trauma System (JTS) guidelines for PFC situations. When patient evacuation is delayed or not available, evidence-based solutions may not be possible. In such cases, experience-based solutions may provide the best option in a compromised setting with limited resources. The CPG recommendations are presented in a "minimum, better, best" format that presents a hierarchy of approaches to address a spectrum of Role 1 situations and available resources. In all cases, this hierarchy builds on itself with “minimum” clinical standards still applicable in scenarios with the “best” available resources.

DCR principles practiced in the presurgical phase of resuscitation have been termed remote damage control resuscitation (RDCR).[12] It is important to distinguish between RDCR and DCR, because capabilities are different in prehospital versus hospital settings.

RECOGNIZING PATIENTS WHO NEED (R)DCR

GOAL

Recognize patients with traumatic hemorrhage who will benefit from implementing DCR early to decrease mortality.

INITIAL SURVEY

Recognize hemorrhagic shock based on rapid examination and recognition of severe injury pattern.

- Injury pattern consistent with massive hemorrhage:
  - Above-the-knee traumatic amputation, especially if associated with pelvic injury

  - Proximal, bilateral, or multiple amputations (including mangled extremity)
  - Clinically obvious penetrating injury to chest or abdomen
  - Uncontrolled truncal or junctional bleeding
  - Uncontrolled major bleeding secondary to large soft-tissue injuries
- Severe trauma with altered mental status (in the absence of brain injury) and/or weak or absent radial pulse.[9]

If initial survey does not indicate severe blood loss, continue assessment, check vital signs, and assess for signs of shock. Recognize hemorrhagic shock on the basis of presence of severe traumatic injury associated with the following:

- Systolic blood pressure (SBP) less than 100mmHg
- Pulse greater than 100 bpm
- Clinical signs of shock, such as cool extremities, delayed capillary refill
- Clinical signs of coagulopathy (e.g., thin, nonclotting bleeding from multiple sites, bleeding from minor wounds such as intravenous [IV] or intraosseous [IO] sites)

ADVANCED CAPABILITIES

When additional laboratory capability and/or ultrasound are available, confirm evidence of hemorrhagic shock using laboratory and/or imaging studies. Do not delay initiating DCR if hemorrhagic shock is clinically suspected: Begin treating immediately once hemorrhagic shock is suspected.

Predictors associated with massive transfusion (i.e. more than 10 units of blood in the first 24 hours) may help identify patients who will require massive transfusion. The more predictors present, the higher the risk of massive transfusion.[13–22]

- Penetrating mechanism
- Positive focused assessment with sonography for trauma (FAST) examination (especially if two or more regions are positive)
- Lactate concentration greater than 4mmol/L on presentation
- Base deficit more than 6mEq/L (base excess less than −6mEq/L)
- pH less than 7.25
- International normalized ratio (INR) 1.5 or greater

HEMORRHAGE CONTROL

GOAL

Stop external hemorrhage and reduce internal hemorrhage to the greatest extent possible. The first step in DCR is limiting blood loss by early and effective hemorrhage control. Interventions to control external hemorrhage are well described in the TCCC guidelines and should be applied as indicated.

- CoTCCC recommended limb tourniquets
- Wound packing

- Pressure dressings
- Hemostatic dressings (Combat Gauze, Celox Gauze, Chito Gauze, and XStat
- Junctional tourniquets
- Pelvic binders

TOURNIQUET NOTES[9]

- Tourniquets (limb and junctional) should be transitioned to pressure dressings within 2 hours when criteria for conversion are met (i.e. the casualty is not in shock, it is possible to monitor the wound closely for bleeding, and the tourniquets are not being used to control bleeding from an amputated extremity). Tourniquets that have been in place longer than 6 hours should not be removed unless close monitoring and laboratory capability are available.

If the tactical situation or injury pattern does not allow for transition of a tourniquet to a pressure dressing, recognize that the priority is life over limb. At times, the decision to leave a tourniquet in place and commit the patient to an amputation is difficult. Consider telemedicine consultation.

- If a tourniquet has been applied for longer than 2 hours and the decision is made to reduce the tourniquet, resuscitation should address hyperkalemia and reperfusion syndrome, similar to crush injuries. See PFC Clinical Practice Guideline (CPG) Crush Syndrome under Prolonged Field Care.[23]

WOUND PACKING NOTES

- If bleeding continues through the hemostatic dressing, reassess the wound. If the wound is fully packed and additional hemostatic dressings are available, consider removing the first dressing and packing a second dressing. If additional space exists in the wound cavity, augment the first dressing with a second hemostatic dressing or gauze dressing.
- The effectiveness of wound packing may be improved when skin closure over the packing can be achieved, either with suture, skin staples, iTClamp®, or application of a chest seal.

EMERGING TECHNOLOGIES

Emerging technologies that may be considered for internal hemorrhage control.

- **Abdominal Aortic and Junctional Tourniquet (AAJT):**
  - This device, although not well studied, is the only noninvasive device available for aortic occlusion. Application of the AAJT (Compression Works; http:// compressionworks.com) may be considered for occlusion of the distal aorta when the injury pattern suggests bleeding in the pelvis and/or junctional lower extremities.
  - If there is bleeding above the level of the umbilicus, in the upper abdomen or chest, application of the AAJT may increase bleeding.
  - Ideally, ultrasound of the abdomen and chest should be performed to look for bleeding before AAJT application.
  - Per manufacturer's guidelines, the AAJT should not be applied in the abdominal position for more than about 30 minutes.

- In the absence of evidence-based protocol, providers may consider: after 15–30 minutes of active resuscitation with blood products and attention to external hemorrhage control, the AAJT should be slowly released.
- If the systolic blood pressure drops below 90mmHg, reinflate the balloon and transfuse an additional unit of blood before releasing the balloon again. Look for other causes of hemodynamic instability.
- Continue to repeat as resources allow until blood pressure stabilizes or arrival at surgical capability.

- **Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA):** Only an advanced resuscitation team with the capabilities for massive transfusion, ultrasound, and arterial access would be expected to obtain the capability for REBOA placement. This device may be considered for occlusion of the aorta at either the position of the diaphragm (zone I, for abdominal hemorrhage or traumatic arrest) or the distal aorta above the aortic bifurcation (zone III, for pelvic and/or junctional lower extremity hemorrhage). Balloon time should be limited to 30 minutes for zone I. Maximum zone III inflation time is not known, but is likely in the range of 2–3 hours. See Joint Trauma System REBOA CPG.[24] Aggressive blood product resuscitation and balloon deflation protocol must be followed, even without surgical intervention.

RESUSCITATION

GOAL

Optimize fluid resuscitation to treat and reverse hemorrhagic shock effectively. Fluid resuscitation principles in PFC are the same as TCCC. Blood products are strongly preferred, and every effort should be made to ensure the capability to transfuse blood products is available near the point of injury. Survival is improved when blood products are transfused within about 30 minutes of injury.[25]

Resuscitation products of choice for casualties in hemorrhagic shock, listed from most to least preferred, are:

- Whole blood
- Plasma, red blood cells (RBCs), and platelets in a 1:1:1 ratio
- Plasma and RBCs in a 1:1 ratio
- Plasma or RBCs alone
- Crystalloid (lactated Ringer's or Plasma-Lyte A).

***Caution**: Crystalloids or Hextend are therapies of last resort and can worsen coagulopathy and bleeding. They should be used only in severely bleeding patients with no radial pulse when no blood products are available. Every effort should be made through training and preparation to ensure availability of stored blood products and ability to draw FWB.*

USE OF WHOLE BLOOD DURING RESUSCITATION

WB PRODUCTS

WB products listed from most to least preferred:

- **Best:** Low-titer group O whole blood (LTOWB) for all
  - Food and Drug Administration–compliant LTOWB supplied by the Armed Services Blood Program.
  - LTOWB drawn from prescreened donors at deployed location, either before mission or during combat casualty care.
    - ***Identify LTOWB donors before deployment.*** Test all personnel with group O blood for anti-A and anti-B antibodies; low titer is defined as immunoglobulin M anti-A and anti-B ratio less than 1:256.
    - Test for transfusion transmitted diseases (TTDs) before deployment and maintain a roster of donors while deployed. Repeat TTD testing every 90 to 120 days when possible.
    - If adequate staff available, confirm ABO group of LTOWB donor prior to transfusing patient using Eldon card or other approved ABO testing kit. If the wrong blood group is transfused, there is a possibility of fatal transfusion reaction.
- **Better:** Administer group-specific WB from prescreened donors
  - Group A to group A, group O to group O and LTOWB for group B and group AB.
  - Group specific for all ABO Group
  - The ABO group of the patient must be confirmed using Eldon card or other approved ABO testing kit. If the wrong blood group is transfused, there is a possibility of fatal transfusion reaction.
- **Minimum:** when prescreened donors for LTOWB or group-specific WB are not available, identify unscreened donors using an Eldon card or other approved ABO testing kit. If the need arises to use blood from unscreened donors. See Appendix B.
  - Group specific (if adequate staff are available, perform testing and verify with second round of testing (i.e. two Eldon cards by two providers for both donor and recipient to be sure that groupings are correct); if the wrong blood group is transfused, there is a possibility of fatal transfusion reaction).
  - If adequate staff or supplies not available or in chaotic situations, use group O for any patient (possibility of transfusion reaction if not titer tested; however, less likely to result in acute hemolytic transfusion reaction than mistaken group-specific transfusion).

Note: *If blood-group testing has not been performed on the casualty before receiving LTOWB, it may not be possible to establish the underlying blood group and they should only receive universal donor blood products. Every effort should be made to obtain a blood sample for later typing before transfusion of LTOWB.*

When WB cannot be obtained, resuscitation using blood products should proceed according to the order of priority for fluid administration, targeting an equal balance of all blood products that are available (RBCs, plasma, platelets).

TRANSFUSION NOTES

- If time and staffing permit, utilize rapid TTD test kits when prescreened donors are not available. Priority for testing should be for HIV and/or any disease of high significance in local area for which test kits are available.

- During resuscitation, blood products and fluids should be warmed using a fluid warmer and infused rapidly.
- WB can be collected and transfused as warm, fresh whole blood (WFWB) or cold-stored whole blood (CS-WB). CS-WB will almost always be LTOWB. See WB CPG for more details.[28]
- WFWB may have some advantages for resuscitation in the PFC environment when prescreened donors are available and the tactical situation allows, because WFWB may be associated with improved survival in trauma patients.[3,4,29] However, CS-WB is more completely tested for infectious disease and does not require additional personnel to collect or donate the blood and should be used preferentially when available.
- Blood and blood products should only be administered by personnel who are trained in the proper procedure and the identification and management of transfusion reactions.
- Usually only one unit of FWB should be collected per donor. However, in extremis, two units may be taken from a single donor. Depending on the size and physical fitness of the donor, a two-unit collection may degrade the tactical performance of a donor, whereas a single unit collection will not. If a second unit is collected from the same donor, consider evacuating the donor with the casualty.
- Freeze-dried plasma (FDP) may be administered to initiate resuscitation while obtaining FWB and/or moving the casualty to a location where blood products are available. The indications to give FDP are the same as the indications for transfusion. FDP is a universal blood product that can be given to any blood group.
- See Appendix A for a summary of blood products provided by the Armed Services Blood Program.

HEMOSTATIC ADJUNCTS

GOAL

Use medications to optimize the casualty's ability to form blood clots.

TXA is an antifibrinolytic medication that helps to stabilize blood clots and may improve survival from hemorrhage. TXA should be administered for casualties with signs of hemorrhagic shock and all casualties who meet criteria for DCR within 3 hours of injury. TXA should not be given more than 3 hours after injury, because this has been associated with increased mortality.[10,26,27]

- **Minimum:** Administer TXA-2gm IV as soon as possible after injury (not more than 3 hours after injury).

  Administration of undiluted TXA by slow IV push is acceptable if supplies or tactical situation prevent 100mL IV infusion. Ideally, slow IV push should be given over 10 minutes; however, it may be given faster when the tactical situation indicates, accepting the risk of transient hypotension. Use greater caution when the casualty is already hypotensive before TXA administration.

- **Best:** administer TXA as soon as possible (within 1 hour) after injury. Administer 2gm of TXA IV/IO ASAP, but NOT later than 3 hours

Calcium administration replaces serum calcium lost during hemorrhage and transfusion of citrated blood products. Calcium helps prevent cardiac dysfunction and hypotension.

- **Minimum:** Administer 1gm of calcium IV/IO during or immediately after transfusion of the first unit of blood product.
- **Better:** With ongoing resuscitation, give additional 1g of calcium after every four units of blood product.

- **Best:** Monitor serum calcium during ongoing resuscitation and administer 1g of calcium for ionized calcium less than 1.2mmol/L.

***Caution**: Calcium gluconate is safer for peripheral use. Calcium chloride may cause severe skin necrosis if extravasation occurs through a partially dislodged IV or IO catheter. The risk of bone necrosis with IO injection of calcium chloride is not known. When using peripheral IV or IO access, use extreme caution to ensure the device is in good intravascular position and no extravasation occurs.*

***Caution:** Do not mix medications and blood products in the same IV line. Use a separate line or flush well between giving medications and blood products.*

MONITORING

GOAL

Maintain adequate oxygenation and ventilation, avoid hypotension, trend response to resuscitation.

VITAL SIGNS

Document vital signs frequently (every 15 minutes initially, then every 30–60 minutes once stable for more than 2 hours) on a flow sheet.[30]

- **Minimum:** Document signs and symptoms that could indicate hypovolemic shock and the response to resuscitation in order of early to late appearance in shock.
  - Mental status
  - Respiratory rate
  - Heart rate
  - Peripheral pulses
  - Blood pressure
  - Also document temperature and pulse oximetry
- **Better:** In addition to minimum requirements, monitor capnometry (displaying end-tidal CO_2 ($ETCO_2$) value, ideally with waveform).
- **Best:** Portable monitor providing continuous vital signs display; capnography

URINE OUTPUT

Urine output (UO) is a valuable indicator of adequate resuscitation from hemorrhagic shock.

- **Minimum:** If patient can void, capture urine in premade or improvised graduated cylinder.
  - Collect all spontaneously voided urine and carefully measure; more than 180mL every 6 hours is adequate for adults.
  - A Nalgene® (Thermo Fisher Scientific, http://www.nalgene.com/) water bottle is an example of an improvised graduated cylinder.

- **Best:** Place Foley catheter and record UO hourly.

LABORATORY TESTS

The utility of laboratory tests in the field setting should not be overlooked for simpler and readily available measurements, like UO. When a portable laboratory device is used, it may be useful to trend the following laboratory test values along with vital signs and UO to obtain a more exact clinical picture.

- **Minimum:** None
- **Better:** Check initial point-of-care lactate concentration.
- **Best:** Monitor one or more of the following laboratory values every 60 minutes until the patient is stabilized, then every 6 hours:
  - Lactate
  - pH and base deficit
  - Hemoglobin/hematocrit
  - INR

Note: *Neurologic examination and vital signs trends are essential to identifying a deteriorating patient with traumatic brain injury (TBI). Monitoring $ETCO_2$ is critical for patients with severe TBI. Ensure this capability is available.*

ASSESSING RESPONSE TO RESUSCITATION

OVERVIEW

Assessing response to resuscitation is a **dynamic process** that is most accurate when all available data are used to paint a composite picture of the casualty. This whole picture is more accurate than any single normal (or abnormal) component.

Casualties will follow one of three trajectories in response to resuscitation: responder, transient responder, or nonresponder.

1. **Responder:** Clinical and objective trends improve after resuscitation and remain stable.
2. **Transient responder:** Trends improve after resuscitation, then decline. This decline should prompt reassessment of hemostatic procedures, assessment for missed hemorrhage, assessment of acidosis or hypothermia, and a trial of repeated resuscitation. If bleeding and factors that affect coagulopathy are controlled, transient responders will likely respond to more resuscitation. A subset of transient responders includes casualties with slow, noncompressible hemorrhage for whom resuscitation can "keep up" with blood loss until surgical hemostasis can be obtained, provided casualty has access to enough blood products and surgery can be obtained.
3. **Nonresponder:** Trends do not improve or continue to worsen after initial trial of resuscitation. Before declaring a casualty to be a nonresponder, reassess hemostatic procedures, assess for missed sources of bleeding, and decompress both sides of the chest (needle decompression/finger thoracostomy/tube thoracostomy). Assess for pericardial tamponade by ultrasound or as a last resort, blind

pericardiocentesis. If major bleeding cannot be controlled, it is not likely that the casualty will respond; this includes noncompressible torso hemorrhage where it is not possible for resuscitation to replace blood loss. If factors affecting coagulopathy (e.g., acidosis and hypothermia) cannot be corrected (with resuscitation and rewarming), it is also unlikely that the casualty will respond.

Note: *If a casualty does not respond to resuscitation, a decision must be made whether to continue resuscitative efforts. If the casualty has worsened, further resuscitation is likely futile. If they have not responded but not worsened, a trial of additional resuscitation if resources are available can be considered to assess whether the initial resuscitation was insufficient.*

Managing a nonresponding casualty is a complex decision that must balance availability of medical resources, demand of other casualties (or contingencies) for those resources, ability of the team to continue the effort of resuscitation, and other factors. It is highly advised to manage in consultation with medical experts (e.g., by telemedicine discussion).

END POINTS OF RESUSCITATION

GOAL

Determine when to stop administration of blood products. It may be difficult to determine when to stop resuscitation and transition to maintenance monitoring and care. Patients may have abnormal vital signs for many reasons. Obtain teleconsultation if targets are not being met and/or trending in the wrong direction.

- **Minimum:** Identify clinical stabilization through ongoing monitoring and examination.

  Slowing heart rate, palpable peripheral pulses, brisk capillary refill, warming extremities, improving mental status (if no brain injury), slowing/cessation of coagulopathic bleeding (wounds and/or IV site bleeding).

- **Better:** In addition to minimum, recognize improved vital signs and objective criteria.
  - **SBP at goal**
    - Goal SBP is approximately 100mmHg if resuscitating with blood products (maintain mild hypotension until definitive bleeding control).
    - In patients with traumatic brain injury, goal SBP is greater than 110mmHg.
    - If unable to resuscitate with blood products, a lower blood pressure goal of SBP from 80–90mmHg is acceptable.
  - **Oxygen saturation** (Spo2) at least 90% (SpO2 >96% is not necessary),[32] fraction of inspired oxygen (Fio2) required should be less than 50%
  - **Temperature** greater than 95ºF (35ºC)
  - **UO** greater than 30mL/h or greater than 0.5mL/kg/h o
- **Best:** In addition to minimum and better, confirm that hemorrhagic shock is resolving, using the following laboratory values:
  - Hemoglobin concentration greater than 8.0g/dL

- Hematocrit greater than 27%
- Lactate concentration less than 2.5mmol/L
- Base deficit less than 4 (base excess greater than −4)

Note: *Improving trends are as important as meeting absolute goals when assessing response.*

If laboratory values do not improve or trend in the wrong direction for two or more different values, either additional resuscitation and/or hemorrhage control interventions are needed or the injury is not survivable given resources and capabilities available. Consider teleconsultation. Expectant management may be appropriate in some circumstances.

DOCUMENTATION

Documentation should consist of the following:[30]

- **Minimum:** TCCC Card (DD1380)
- **Better:** PFC flowsheet

During prolonged care, once all available time blocks on the TCCC card are filled and evacuation to higher level of care is not imminent, transition to PFC flowsheet.

- **Best:** After action report in addition to above

Note: *Blood products transfused, patient and donor identification must be reported to the COCOM Joint Blood Program Office (JBPO). Recipients of emergency collected whole blood must be enrolled into a follow-up infectious disease monitoring program (contact JBPO or ASBP for guidance).*

PEDIATRIC CONSIDERATIONS

- Critically wounded or ill pediatric patients are more difficult for the Role 1 provider or medic because of the lack of regular exposure to pediatric care. It is recommended that a pediatric reference card or Broselow tape be available to identify pediatric ranges for vital signs, drugs, and supplies.
- Total circulating blood volume in children can be estimated at 70–80mL/kg for children younger than age 12 years.[31] In very young or small children, this is a very small volume. For example, an average 1-year-old American child weighs 10–11kg and has a total blood volume approximately equivalent to two units of blood. Underestimating blood loss percentage and over resuscitating should both be avoided.
- As in adults, do not hesitate to use an IO catheter as the first and primary line for initial resuscitation. A second IV or IO line should be started as soon as possible for additional drug administration.
- TXA is indicated in pediatric casualties. The dose is 15mg/kg TXA loading dose (maximum, 1g) over 10 minutes followed by 2mg/kg/h for 8 hours (maximum, 1g).[33]

To prepare the second dose as a drip, inject 15mg/kg TXA into a 100mL bag of NS. Using a dial-a-flow drip set, place the drip rate at 13 mL/h (OR by drip count: 1 drip every 5 seconds for 60 drip/mL tubing; 1 drip every 18 seconds for 15 drip/mL tubing; 1 drip every 27 seconds for 10 drip/mL tubing).

- Similar to adults, early transfusion therapy should be started sooner rather than later. LTOWB and FWB are both acceptable to give to children with life-threatening hemorrhage. There is no contraindication to

the use of any WB product in children. The initial dose for blood is 10mL/kg, but in children with massive hemorrhage, blood products can be given in higher doses as fast as needed to gain hemodynamic stability. Massive transfusion in pediatrics has been defined as more than 40mL/kg of blood products in 24 hours. WB is easier to titrate effectively in children than component therapy.

- Children are at high risk of developing hypocalcemia, hypomagnesaemia, metabolic acidosis, hypoglycemia, hypothermia, and hyperkalemia during transfusion. Therefore, frequent monitoring (every hour if possible) and correction of acid/base status, electrolytes, and core temperature is indicated during the resuscitation of pediatric casualties, when available.

END OF LIFE/EXPECTANT MANAGEMENT

Determining futility of care: despite best efforts, certain injuries are not survivable in austere environments. The tactical situation, casualty clinical condition, and operational constraints (e.g., mass casualty incidents, logistics) may warrant the consideration of ceasing ongoing, aggressive resuscitative efforts.

The provider must use all their operational knowledge to determine the utility of ongoing resuscitation. As a guide only, examples of wounds with low chance of survival include:

- Cranial injuries with exposed brain matter (exception may be isolated frontal lobe injuries) or severe TBI with signs of herniation (i.e. dilated pupils, hypertension plus bradycardia) or Glasgow Coma Scale score .[3–5]
- Penetrating thoracic or abdominal injuries that are hypotensive or nonresponsive after:
  - two units blood transfusion
  - bilateral chest decompression (needle decompression/finger thoracostomy/tube thoracostomy)

    and
  - assessment for pericardial tamponade
- Junctional amputations with pelvic disruption
- Out-of-hospital cardiac arrest (despite bilateral chest decompression), especially if surgical resuscitation is more than 10 minutes away.
  - Blunt trauma mechanism without organized activity on cardiac monitor
  - Cardiopulmonary resuscitation for longer than 5 minutes
  - No cardiac motion observed on FAST examination or palpated with left finger thoracostomy
  - Cardiac monitoring reveals:
  - Asystole
  - No organized rhythm
  - Wide complex/idioventricular rhythm
- Cervical spine trauma with cardiovascular collapse
- Obvious massive trauma, such as total body disruption and decapitation
- Nonresponders

Before cessation of resuscitation attempts by the provider, every attempt should be made to contact medical direction for input. If contact with higher medical direction is not feasible, then the on-scene provider must use

their best judgment for ongoing resuscitation attempts. This may include an assessment of available resources, timing of evacuation, and the clinical condition of all the patients requiring the attention of the provider making the decision. It will not always be possible to save all team members.

A determination that further attempts to save a life are futile does not necessarily mean cessation of clinical care for the patient. All reasonable interventions to reduce pain and suffering, short of hastening death (e.g., not giving a lethal dose of opiates) should be provided. At times, agonal respirations and bodily movement can take place in the dying process; be prepared for this in the sight of comrades and be prepared to explain this. This is not a reason to continue resuscitative efforts.

If a casualty dies, all medical interventions should be left in place if feasible. If supplies may be needed for future casualties and resources are critically limited, it may be necessary to reuse medical devices (e.g., cricothyrotomy kits, chest tubes).

After death, a casualty should not be used as a blood donor for surviving casualties. Every attempt should be made to find alternate donors for any surviving casualties. Transfusing blood from a deceased casualty may result in transfusing acidotic and hypocoagulable blood, thus worsening the surviving casualty's hemostatic physiology and possibly causing death.

Providers facing the dilemmas around patient death and cessation of resuscitative efforts should also be cognizant of the effects on team members, other patients, and on themselves. Various strategies for coping with these challenges may be appropriate in different circumstances. A full exploration of the topic is beyond the scope of this CPG; however, some consideration of these issues should be built into individual and unit training for PFC scenarios.

APPENDIX A: BLOOD PRODUCTS AVAILABLE – ARMED SERVICES BLOOD PROGRAM

			Temperature for		Transport	
Product	**Volume, mL**	**Shelf Life**	**Storage**	**Transport**	**Bulk: Collins Box (storage requirements)**	**Tactical** (Storage time when preconditioned to −18°C)**
Warm fresh whole blood*	450	24 hours at RT If refrigerated in 8 hours (see CSWB)	1–6°C	N/A	N/A	N/A
CSWB (LTOWB)	450–500	CPD: 21 days CPDA-1: 35 days 24 hours at RT	1–6°C	1–10°C	21 units/each ~14lb wet ice every 48 hours	2 units (24–48 hours)
Red blood cells	310	CPD/AS5: 42 days CPDA-1: 35 days	1–6°C	1–10°C	30 units (~14 lb wet ice every 48 hours)	2-4 units depending on container (24–48 hours)
Frozen plasma	220	Frozen: 1 year	Frozen: ≤–18°C	Frozen: maintain frozen	Frozen: 15 units (~20–30lb dry ice every 48 hours)	Frozen: N/A
		After thawing: 5 days if stored at 1–6°C	Thawed: 1–6°C	Thawed: 1–10°C	Thawed: 30 units (~14lb wet ice every 48 hours)	Thawed: 2–4 units depending on container (24–48 hours)
Liquid plasma	220	CPD: 26 days CPDA-1: 40 days	1–6°C	1–10°C	30 units (~14lb wet ice every 48 hours)	2-4 units depending on container (24–48 hours)
Platelets, RT	150–400	7 days	20–24°C	20–24°C	N/A	N/A
Platelets, cold-stored	150–400	10 days	1–6°C	1–10°C	4 units (~14lb wet ice every 48 hours)	2 units (24–48 hours)
Cryoprecipitate	15 (single) 150 (pooled)	Frozen (single & pooled): 1 year	Frozen: ≤–18°C	Frozen: maintain frozen	Frozen: 15 units (~20–30lb dry ice every 48 hours)	N/A
		Thawed: within 6 hours thawed or 4 hours pooled if stored at 20–24°C	Thawed: 20–24°C			
Freeze dried plasma***	220 ml reconstituted	2 years	12–25°C	Ambient temperature	N/A	N/A

CPD, citrate-phosphate-dextrose; CPDA-1, citrate-phosphate-dextrose-adenine; CSWB, cold-stored whole blood; LTOWB, low-titer group O whole blood; RT, room temperature; N/A, not applicable.
*Approximate distribution of blood types in US population: type O, 45%; type A, 40%; type B, 11%; type AB, 4%.
**Tactical blood storage: Options include Golden Hour Container, Golden Hour Medic Container. Other transport containers may also be available. Ensure all blood transport containers are validated for use in coordination with Army Services Blood Program.
***The US Food and Drug Administration granted an emergency use authorization for French freeze-dried plasma to the US military on 9 Jul 2018, however supply is limited.

APPENDIX B: UNSCREENED DONOR PROCEDURES

When an emergency situation does not allow complete donor assessment according to the Joint Trauma System Whole Blood Transfusion Clinical Practice Guidelines,[13] the following rapid donor screen may be used. Relaxing the donor acceptance criteria will increase the risk of transfusion-transmitted disease. The decision is a risk-benefit analysis.

Primary Triage (question as a group)

Serial	Question	Yes	No	Action
1	Do you want to give blood?			Disqualify if NO
2	Have you given blood before?			If YES, consider early selection
3	In the past 48 hours, have you taken aspirin, Motrin, or other NSAID?			If YES, donor priority is after those who answer NO

Secondary Triage (question potential donors individually)

Serial	Question	Yes	No	Action
4	Are you unwell now? New fever/diarrhea/vomiting Chronic medical condition and not well			Disqualify if YES
5	Have you ever had cancer, heart problems, bleeding conditions, or lung disease?			Disqualify if YES
6	Have you had a blood transfusion or blood products in the last year?			Disqualify if YES Accept after 1 year
7	Are you living with hepatitis B or C, HIV/AIDS, OR living with anyone with these conditions?			Disqualify if YES
8	Have you ever been refused as a donor or told not to donate blood? (A past history of treated anemia may be acceptable)			Disqualify if YES
9	Male donors only: Have you ever had sex with another male?			Disqualify if YES
10	Have you ever used needles to take drugs, steroids, or anything not prescribed by your doctor?			Disqualify if YES
11	Are you currently pregnant or breastfeeding?			Disqualify if YES
12	Conduct a physical examination. Check: temperature/rash/ malnutrition/pallor/jaundice/cyanosis/shortness of breath/ intoxication from alcohol or drugs/veins			Disqualify any potentially unwell donor or donors with very difficult veins
13	Have you ever had Malaria, Chagas, or Babesiosis?			Disqualify if YES
14	Have you ever received money, drugs, or other payment of sex?			Disqualify if YES

Risk Triage (question potential donors individually)

Score	Questions	Subtotal	Notes
Blood donation history			
1	Regular donor		Optimum
2	Previous donor		
3	Nondonor		
Veins and body weight			
1	Good lateral (outer) vein		Optimum
2	Poor or difficult vein		
3	<60kg		
Travel			
1	No travel in the countries below in the last 6 months		Optimum
2	South America		
4	Asia and Africa		
Lifestyle			
1	Sex with one partner		Optimum
3	Sex with multiple partners but protected		
—	Sex with a sex worker or in exchange for money/drugs		Avoid for 12 months
Serious medical conditions			
1	None		Optimum
3	Past or present serious medical conditions but managed and well		
3	Untreated current medical conditions but well		
	TOTAL		

Add up score and record total: Lowest score = Lowest risk. Use point-of-care test for transfusion transmitted infections. Eliminate and counsel any positives. Blood type donor and recipient and document results.

APPENDIX C: WHOLE BLOOD DRAW AND STORAGE PLANNING GUIDE

(Provides for 25 whole-blood collections from donors and 25 recipients)

Donor Testing	Transfuse to Patient

• Eldon military kit
  - 2 x Eldon bags, 50 Eldon cards
  - 200 x Eldon sticks
  - 50 x Standard lancets
  - 50 x Skin cleansing swabs
  - 50 x Cotton balls
  - 2 x Plastic droppers
  - 2 x Set of instructions
• 25 x 10mL prefilled NS syringe
• 25 x Point-of-care disease testing kit
  - HIV, HCV, HBV, RPR, malaria, area specific (e.g. Ebola)
• 50 x red top and 100 x purple top tubes for confirmatory laboratory testing
• 2 x Permanent marker
• 5 x Nitrile glove, L
• 2 x Surgical tape
	• Fluid warming device
	• 25 x IV catheter, 18G x 1.25"
	• 25 x IO catheter, 18G
	• 25 x 100mL NS
	• 25 x Y-type administration set with filter
	• 2 x Pressure infusing device
	• 25 x OPSITE wound dressing

Donor Blood Draw	**Monitor Patient**
• 25 x Single collection 450mL CPD/CPDA-1 blood pack • 25 x 1mL syringes with 25G needles • 5 x Kelly forceps for tube clamping • 1 x 10" 550 cord • 200 x Alcohol pads • 25 x 18G needle • 200 x Woven gauze sponges • 25 x OPSITE wound dressing • 25 x Blood bag labels	• 2 x Thermometer • 1 x BP cuff • 1 x stethoscope • 2 x Spo_2 monitor • 2 x CO_2 monitor • 2 x Foley catheter
Storage	**Drugs**

• Cooling unit (maintain 6°C)
• White board (to record blood types and draw dates)
	• 10 x 1:1,000 epinephrine
	• 10 x 50mg diphenhydramine
	• 10 x 1g calcium
	• 25 x gm TXA
	  - 25 x 10mL syringe
	  - 25 x 18G needle
	  - 25 x 100mL NS
	  - 25 x administration set

APPENDIX D: DAMAGE CONTROL RESUSCITATION IN PROLONGED FIELD CARE: SUMMARY TABLE

Goal	Minimum	Better	Best
Recognizing casualties who require DCR			

Recognize patients with traumatic hemorrhage who will benefit from early DCR.	Initial survey, recognize need for DCR based on:
	• Severe injury pattern: proximal, bilateral, or multiple amputations; penetrating injury to chest/abdomen; pelvic or junctional hemorrhage
	• Altered mental status (in absence of TBI)
	• Weak/absent radial pulse
		If initial survey does not indicate severe blood loss, continue to assess for signs of shock:
		• SBP <100mmHg
		• Pulse >100 bpm
		• Physiologic signs of shock (e.g., cool extremities, delayed capillary refill)
		• Clinical signs of coagulopathy (e.g., bleeding from minor wounds such as IV or IO sites)
			If uncertain, confirm using laboratory and/or imaging studies.
			Predictors of massive transfusion (more predictors = higher risk)
			• Penetrating mechanism
			• Positive FAST examination (especially if 2 or more regions)
			• Initial lactate >4mmol/L
			• Base deficit >6mEq/L
			  • pH <7.25
			  • INR≥1.5

– Do not delay initiating DCR if hemorrhagic shock is clinically suspected			
Hemorrhage control			
Stop external hemorrhage and reduce internal hemorrhage per TCCC guidelines.	• Limb tourniquets • Wound packing • Pressure dressings • Hemostatic dressings • Junctional tourniquets • Pelvic binders		Emerging technologies: • AAJT • REBOA • ≤30 minutes inflation time, see protocol for use.
Resuscitation—products of choice for casualties in hemorrhagic shock, listed from most to least preferred			
• Whole blood • Plasma, RBC, and platelets in a 1:1:1 ratio • Plasma and RBCs in a 1:1 ratio		• Plasma or RBCs alone • Crystalloid (lactated Ringer's or Plasma-Lyte A)	

Goal	Minimum	Better	Best
Resuscitation—use of whole blood			
Maintain vital-organ perfusion and minimize acute coagulopathy of trauma through administration of WB within 30 minutes of injury.	When prescreened donors or LTOWB are not available, transfuse: • Type-specific WB (verify using Eldon card x2; if wrong blood type transfused, possibility of fatal transfusion reaction). • If adequate staff or supplies not available or in chaotic situations, use Group O WB for any patient (possibility of transfusion reaction if not titer tested).	Type-specific WB drawn from prescreened donors in the following order of preference: • Group A to Group A, Group O to Group O and LTOWB for Group B and Group AB. • Type specific for all ABO Groups.	LTOWB for all • FDA-compliant cold-stored LTOWB drawn from prescreened donors • LTOWB drawn from prescreened donor at deployed location, either before mission or during combat casualty care
Hemostatic adjuncts			
TXA			
Administer TXA early after injury to reduce fibrinolysis and stabilize clot.	TXA 2g IV as soon as possible after injury. May administer undiluted by slow IV push when necessary.		• TXA -2gm IV as soon as possible after injury
*– TXA should be administered for casualties with signs of hemorrhagic shock and all casualties who meet criteria for DCR within 3 hours of injury. TXA **should not** be given more than 3 hours after injury. **Rapid IV push may cause hypotension.***			
Calcium			
Maintain calcium levels lost during hemorrhage and transfusion of citrated blood products to prevent cardiac dysfunction and hypotension.	Administer 1g of calcium IV/IO during or immediately after transfusion of the first unit of blood product.	With ongoing resuscitation, give additional 1g of calcium after every four units of blood product.	Give initial dose then monitor serum calcium level during ongoing resuscitation and administer 1g of calcium for ionized calcium level <1.2mmol/L.
– Calcium gluconate is safer for peripheral use. Calcium chloride may cause severe skin necrosis if extravasation occurs through a partially dislodged IV or IO. The risk of bone necrosis with IO injection of calcium chloride is not known. When using a peripheral IV or IO catheter, use extreme caution to ensure that the device is in good intravascular position and no extravasation occurs. ***– Do not mix medications and blood products in the same IV line. Use a separate line or flush well between giving medications and blood products.***			

AAJT, Abdominal Aortic and Junctional Tourniquet; CPD, citrate-phosphate-dextrose; CPDA-1, citrate-phosphate-dextrose-adenine; CPG, clinical practice guideline; DCR, damage control resuscitation; $EtCO_2$, end-tidal CO_2; FAST, focused assessment with sonography for trauma; FDA, Food and Drug Administration; HBV, hepatitis B virus; Hct, hematocrit; HCV, hepatitis C virus; INR, international normalized ratio; IO, intraosseous; IV, intravenous; LTOWB, low-titer group O whole blood; NS, normal saline; PFC, prolonged field care; RBC, red blood cell; REBOA, resuscitative endovascular balloon occlusion of the aorta; SBP, systolic blood pressure; Spo_2, oxygen saturation; TBI, traumatic brain injury; TCCC, Tactical Combat Casualty Care; TXA, tranexamic acid; UO, urine output; WB, whole blood.

Goal	Minimum		Better	Best
Monitoring				
Vital signs	• Mental status • Blood pressure • Respiratory rate • Heart rate	• Peripheral pulses • Pulse oximetry • Temperature	Minimum + capnometry	Portable monitor with continuous vital signs display; capnography
UO goal: UO ≥30mL/h (or 0.5mL/kg/h)	Collect all spontaneously voided urine and carefully measure; >180mL every 6 hours is adequate for adults.			Place Foley catheter and record UO hourly.
Laboratory tests	None		Check initial POC lactate level	Lactate, pH, base deficit, hemoglobin/ Hct, INR measured every 60 minutes until stabilized, then every 6 hours
– Neurologic examination and vital signs trends are essential to identifying a deteriorating patient with TBI. – Monitoring $EtCO_2$ is critical for patients with severe TBI; ensure this capability is available.				
Assess response to resuscitation				
• Responder: Clinical and objective trends improve after resuscitation and remain stable. • Transient responder: Trends improve after resuscitation, then decline. • Nonresponder: Trends do not improve or continue to worsen after initial trial of resuscitation (see End-of-life/expectant management in CPG text).				
End points of resuscitation				
Determine when to stop administration of blood products and transition to maintenance monitoring and care.	Clinical stabilization indicated by: • Slowing heart rate • Improved peripheral pulses, brisk capillary refill • Warming extremities • Improving mental status (if no TBI)		In addition to minimum, recognize improved vital signs and objective criteria. • SBP at goal • SpO2 >92%, FiO2 required <50% • Temperature >95ºF (35ºC) • UO >30 mL/h or >0.5mL/kg/h	In addition, confirm by laboratory values that hemorrhagic shock is resolving. • Hemoglobin >8.0 g/dL • Hematocrit >27% • Lactate <2.5mmol/L • Base deficit <4
– Goal SBP ~100mmHg if resuscitating with **blood products**; if unable to resuscitate with blood products, goal SBP is 80–90mmHg. In TBI, goal SBP >110mmHg**.** – Obtain teleconsultation if goals are not being met and/or trending in the wrong direction.				
Documentation				
Adequately capture clinical information to ensure continuity of care	TCCC Card (DD1380)	PFC flowsheet: once all time blocks on the TCCC card are filled and evacuation to higher level of care is not imminent, transition to PFC flowsheet.		TCCC care (DD1380) + PFC flowsheet + after-action report
– Blood products transfused, patient and donor identification must be reported to the COCOM Joint Blood Program Office (JBPO). Recipients of emergency collected whole blood must be enrolled into a follow-up infectious disease monitoring program (contact JBPO or ASBP for guidance).				

APPENDIX E: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

The Prevention of Deep Venous Thrombosis – Inferior Vena Cava Filter (CPG ID: 36)

To establish guidance for 1) anti-thrombotic therapy for the prevention of deep venous thrombosis (DVT) and pulmonary embolism (PE) and 2) the management of inferior vena cava filters (IVCs) placed in the combat theater for the purpose of either primary or secondary prophylaxis of pulmonary embolism.

Appendix A: Prevention of Venous Thromboembolism Guidelines 9
Appendix B: IVCF Recommendations 11
Appendix C: Additional Information Regarding Off-label Uses in CPGs 12

BACKGROUND

Trauma patients are known to be at high risk for Venous Thromboembolism (VTE) including Deep Venous Thrombosis (DVT) and Pulmonary Embolism (PE). Major trauma patients can have up to 58% incidence of DVT.[1] Sevitt and Gallagher reported an even higher incidence (65%) in injured and burned patients and reported a 16.5% incidence of PE found at autopsy in this cohort of patients.[2,3]

In addition to the hypercoagulable state induced by severe injury in trauma, combat casualties have additional risk factors for DVT, including:[1,4-8]

- Early transfusion of blood products (≤24 hours);
- Transfusion of old blood (≥28 days);
- Multiple and/or above the knee amputations

The use of Fresh Frozen Plasma (FFP) outside of large volume blood product transfusion (less than 4 U PRBC's) incurs an increased risk of VTE.[9] Early prophylaxis in this patient population is recommended provided hemostasis has been achieved.

The nature of the current combat theater has provided our deployed medical team's ample opportunity to care for children injured as non-combatants. The incidence of DVT after trauma is much lower (6.2%) than that of adults in the civilian literature.[10] The presence of multiple risk factors including immobility and central venous line, however, were associated with the development of DVT in pediatric trauma patients.

There is an increasing recognition of DVT in individuals who complete an extended period of travel on an airplane. One study noted a 10% prevalence of asymptomatic DVT in individuals undergoing flights of 8 hours or more.[11] Combat casualties are at high risk for VTE during recovery and evacuation, which can be associated with long flights and immobility, thus it is important to start VTE prophylaxis as soon as clinically possible.[12]

Landstuhl Regional Medical Center is uniquely positioned to receive patients who have undergone extensive periods of travel prior to admission.

Different medical societies and working groups have published varying recommendations for DVT prophylaxis.[13,14] The clinical guidance recommended here represent the guidelines with either a higher level of scientific evidence supporting the recommendation, or the more conservative recommendation. It is recommended to begin DVT prophylaxis therapy as soon as coagulopathy is corrected in patients not otherwise at increased risk of bleeding.

RECOMMENDATIONS FOR DVT PROPHYLAXIS

Unless contraindicated by lower extremity injury, all trauma patients should receive:

1. Sequential Compression Device (SCD) therapy as primary DVT prophylaxis in addition to;
2. Low dose Unfractionated Heparin (UFH)[13-15]; or
3. Low Molecular Weight Heparin (LMWH), Enoxaparin 30mg subcutaneous (SC) twice daily.[16]
4. Alternatively, low does LMWH such as Dalteparin 5000 U SC or Enoxaparin 40mg SC can be given daily and in one study has a lower incidence of DVT when compared to 30mg BID dosing in post-operative patients.[14,17,18]

5. Unfractionated Heparin (5000 U) administered subcutaneously three times daily has been demonstrated to be as effective as or at least non-inferior to Enoxaparin in the prevention of DVT in trauma patients.[19,20]

Consideration should be given to the use of LMWH in patients with impaired renal function (CrCL=30ml/min or less), as there is a concern for LMWH accumulation and increased risk of bleeding.

1. Despite this concern, no clear evidence exists for dose modification or contraindication to the use of LMWH for DVT prophylaxis in renal impaired patients.[21]

2. Godat et al. reported, however, that trauma patients who are considered to be at the highest risk to develop VTE (especially spinal cord injury with/without pelvic fracture) are at the greatest risk during the first three months after injury and that this risk decreases at six months post injury.[23]

The role of **duplex ultrasound** in the diagnosis of DVT should be reserved for the symptomatic patient. Serial screening duplex ultrasound for the diagnosis of DVT is not recommended.[14]

CHEMICAL DVT PROPHYLAXIS

Provided coagulopathy and ongoing bleeding is corrected, chemical DVT prophylaxis (<48 hours post injury) has been shown to be safe after blunt solid organ injuries.[24,25]

Chemical DVT prophylaxis (<48-72 hours) following traumatic brain injury with intracranial hemorrhage does not increase the progression of intracranial bleed.[26,27] Prior to starting chemical DVT prophylaxis, you should:

1. Consult a Neurosurgeon.

2. Obtain a stable CT scan of the head at 24 hours post injury.

Prophylaxis should be withheld in the setting of progression of intracranial hemorrhage or presence of an intracranial monitor.

Modification of enoxaparin dosing to 40mg daily in the combat casualty requiring an epidural pain catheter does not increase the incidence of venous thromboembolism.[28]

Inferior Vena Cava Filter (IVCF) placement in the combat theater may be used for:

1. Primary Prophylaxis (no evidence of VTE disease at the time of placement).

2. Secondary Prophylaxis (documented DVT) of PE in the polytrauma patient.

Patients felt to be at particularly **high risk for VTE development** and who have a clinical contraindication to prophylactic anticoagulation are the most likely to have an IVCF placed.

Most series examining the use of **IVCF placement for primary prophylaxis of PE** in the trauma patient support a low rate of subsequent PE (1.6%), although the studies are of variable design and a strong consensus supporting this clinical practice cannot be made based upon available data.[29]

There is no evidence that **prophylactic use of IVCF** is associated with a decreased PE rate or fatal PE rate. It should be noted that when IVCF are placed they are done so to prevent FATAL Pulmonary Emboli as DVT and PE still can occur.[30-34]

IVCF has no benefit in the prevention of DVTs and may be associated with the development of IVC and Deep Venous Thrombosis.[14,35]

RETRIEVABLE INFERIOR VENA CAVA FILTERS (RIVCF)

The vast majority of IVCF devices placed in the combat theater are Retrievable Inferior Vena Cava Filters (RIVCF).

RIVCF are preferred to avoid some of the long-term complications of filter placement. Additionally, many patients only need this form of VTE prophylaxis for a defined period of time early after injury.

Despite successful removal of IVCF beyond 180 days and high success and low complication rate for attempted **IVCF removal**, rates of eventual removal of RIVCFs in multiple studies of trauma patients in the United States have been as low as 14% to 22%.[36,37,38,39,40]

Combat injured patients from Operation Iraqi Freedom (OIF) and Operation Enduring Freedom (OEF) who had RIVCFs placed have an overall retrieval rate of 18%.[41]

It should be noted however; that the majority of patients was lost to follow up or did not have filters removed due to ongoing indications for use (82%). Therefore, the overall retrieval technical success rate may be much higher. Most series support removal of the most commonly used RIVCFs as early as they are no longer necessary and no later than approximately three months.[42] While it is possible to remove any of these later than this time period, the technical success declines significantly as potential complications associated with removal increase. Clear electronic documentation and a dedicated tracking system at the final CONUS MTF must be in place to improve retrieval rates and minimize loss to follow up.[43]

EDUCATION AND TREATMENT

Refer to Appendix A for specific guidance on different subsets of patients after various surgical procedures.

Refer to Appendix B for additional recommendations regarding IVC filters.

AEROMEDICAL EVACUATION CONSIDERATIONS

1. Aeromedical Evacuation (AE) from any area of responsibility to continental U.S. can require multiple flights over the course of days before the patient arrives at his or her final destination.
2. There is a clear association between long-distance travel and an increased risk of VTE, even in a "healthy traveler."
3. Stresses of flight such as prolonged immobility and decreased humidity may contribute to VTE formation, especially in groups who already carry a high risk (trauma patients, recent surgeries, long bone fractures, smokers, pregnancy or post-partum, recent Myocardial Infarction, active cancer, presence of splint or cast, etc.).
4. Prophylaxis is essential to reduce the risk of VTE associated morbidity and mortality in all AE patients.
   a. AE crews will encourage patient ambulation every 2 hours for patients whose condition allows.
   b. SCD use should be universal for inpatients unless contraindicated by injury pattern. The Kendal SCD Express compression system is approved for use on military aircraft.
   c. Chemical VTE prophylaxis is also recommended as above for all trauma or medical inpatients unless specifically contraindicated by the medical condition such as ongoing bleeding or coagulopathy.
5. AE Patients with KNOWN acute VTE should be treated prior to flight unless there is a clear contraindication.
   a. Treatment depends on the clinical situation, but may include low-molecular-weight Heparin, Fondaparinux, oral Xa inhibitors, or Unfractionated Heparin.
   b. Oxygen and continuous pulse-oxygenation monitoring should be available during AE for patients with known VTE in case supportive measures are needed.
   c. In the case of known or suspected Pulmonary Embolism, a Cabin Altitude Restriction should be considered to mitigate the effects of altitude on oxygenation and respiration.

d. Addition of a Critical Care Air Transport Team should also be considered in cases of PE with significant respiratory or hemodynamic compromise.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All trauma patients admitted to Role 2 or higher.

INTENT (EXPECTED OUTCOMES)

1. All patients in population of interest receive DVT prophylaxis with sequential compression device within 24 hours of injury.

2. All patients in population of interest start chemoprophylaxis (Heparin, Lovenox) within 48 hours of injury or contraindication documented.

3. When IVCF is inserted, there is documentation in the medical record regarding the indication for procedure, whether the IVCF is retrievable, manufacturer, brand, serial number, lot number, and exact location of placement.

4. Retrievable IVC filters are removed within 6 months.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who start DVT prophylaxis with sequential compression device within 24 hours of injury.

2. Number and percentage of patients in the population of interest who receive DVT chemoprophylaxis within 48 hours (Heparin, Lovenox) or have contraindication documented.

3. Number and percentage of patients who receive IVC filter placement who have complete documentation of indication for procedure, whether the IVCF is retrievable, manufacturer, brand, serial number, lot number, and exact location of placement.

4. Number and percentage of retrievable IVC filters placed that are removed within 6 months.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief, JTS Program Manager and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

All Health Care Providers will:

- Become familiar with the guidelines for the prevention of DVT (see Appendix A).
- Appropriately manage patients who may be at risk of developing DVT.
- Provide feedback on these guidelines and suggestions for changes to the CPG to the JTS Chief.

The senior surgeon and/or Intensivist at each Role 3 facility will:

- Review all thromboembolic events in the Level III facility to assess ways to reduce the risk to the patient.
- Coordinate with the JTS Performance Improvement Division Chief on the appropriateness of the guidelines being used and provide input for updates on an as needed basis.

APPENDIX A: PREVENTION OF VENOUS THROMBOEMBOLISM GUIDELINES

RISK GROUP	PROPHYLACTIC MEASURES
TRAUMA PATIENTS	
▪ Emergency trauma surgical procedures in patients with prohibitive risk of bleeding, or ongoing coagulopathy	▪ SCD (sequential compression device) until able to be anticoagulated (ideally start Lovenox within 12 hours of cessation of coagulopathy); see IVC filter and Duplex screening sections below.
▪ Emergency trauma surgical procedures in all patients, except patient with prohibitive risk of bleeding (once coagulopathy not present)	▪ SCD (unless contraindicated by injury) + Lovenox 30 mg SC BID or 40mg SC QD; alternatively Heparin 5000 U SC q 8 hours
▪ Isolated major orthopedic surgery of extremities, spine, and pelvis	▪ SCD (unless contraindicated by injury) + Lovenox 30 mg SC BID
IVC FILTER PLACEMENT	
Patients with: 1. Recurrent PE despite full anticoagulation 2. Proximal DVT and contraindications for full anticoagulation 3. Proximal DVT and major bleeding while on full anticoagulation 4. Progression of iliofemoral clot despite anticoagulation Patients with established DVT or PE and: 5. Large free-floating thrombus in the iliac vein or IVC 6. Following massive PE in which recurrent emboli may prove fatal 7. During/after surgical embolectomy Very High Risk Patients: those who cannot receive anticoagulation because of increased bleeding risk and : 8. Severe closed head injury (GCS<8) 9. Incomplete spinal cord injury with paraplegia or quadriplegia 10. Complex pelvic fractures with associated long-bone fractures 11. Multiple long-bone fractures	▪ Placement of retrievable IVC filter (RIVCF) ▪ **Document if the IVCF is retrievable or not, manufacturer, brand, MRI compatibility, serial number, lot number and exact location** in record and TMDS; PE may still occur despite IVC filter ▪ "Extended" indications for placement of IVC filter for patients with established DVT or PE ▪ Consideration of placement of prophylactic placement of IVC filter.
ROLE OF DUPLEX SCREENING	
▪ Asymptomatic patients	▪ Serial duplex ultrasound imaging of high-risk patients is not recommended.
▪ Symptomatic patients	▪ Duplex ultrasound may be used without confirmatory venography.
GENERAL, VASCULAR, UROLOGIC SURGERY	
LOW RISK:	
Minor procedure in patients < 40 years, no risk factors	Early mobilization
MODERATE RISK:	
▪ Minor procedure with additional risk factors for thrombosis; ▪ Non major surgery in patients 40-60 years, with no additional risk factors; ▪ Major surgery in patients < 40 years with no additional risk factors)	▪ SCD + Unfractionated Heparin 5000 units SCq 8 hours or Lovenox 40 mg SC QD ▪ Chemical DVT prophylaxis is withheld in patients with high risk of bleeding.

RISK GROUP	PROPHYLACTIC MEASURES
HIGH RISK:	
▪ Non major surgery in patients > 60 years or have additional risk factors; ▪ Major surgery in patients > 40 years or have additional risk factors	▪ SCD + Unfractionated Heparin 5000 units SC q 8 hours or Lovenox 40 mg SC QD ▪ Chemical DVT prophylaxis is withheld in patients with high risk of bleeding.
NEUROSURGERY	
▪ Intracranial neurosurgical procedures ▪ High Risk neurosurgery patients	▪ SCD ▪ Chemical DVT prophylaxis following stable CT scan in consultation with neurosurgeon

APPENDIX B: IVCF RECOMMENDATIONS

1. All IVCFs placed in the combat theater should be retrievable.

2. Documentation detailing the ICVF brand, model, MRI compatibility, and exact location of placement should be documented in ALTHA T or TC2.

3. All RIVCFs placed in the combat theater should be removed as soon as contraindications to chemical prophylaxis of VTE disease no longer exist or there is no longer a need for VTE prophylaxis. Exceptions include those that were placed for secondary prophylaxis in a patient who demonstrated new VTE disease while on therapeutic anticoagulation or in patients who are still deemed to be high risk.

4. All RIVCFs should be removed within three months unless a long term indication for their continued use is present.

5. The decision to remove an RIVCF placed in the combat theater (versus leaving it in place permanently) should be made at the first CONUS Level V MTF the patient transitions through while returning from deployment. When possible, the removal should take place at this same facility prior to transition to the next level of care. This approach decreases the chance that a decision will be deferred until removal becomes technically prohibitive.

6. **The presence of a RIVCF in a patient receiving care at the Level IV MTF should be made known to the receiving Level V MTF. Typically, retrieval of the RIVCF will be accomplished at the Level V MTF.**

7. Any patient with a known DVT and without a current contraindication to therapeutic anticoagulation who has an IVCF in place should receive full dose anticoagulation. This is preferably accomplished with Coumadin to target an INR of 2.0-3.0. If further surgical procedures are planned, consideration may also be given to the use of low molecular weight heparin dosed at 1 mg/kg bid or an unfractionated heparin drip until such time as the use of Coumadin is felt to be appropriate.

8. The presence of an IVCF, brand, model, MRI compatibility, whether or not it is retrievable, its exact location and the date of insertion should be clearly annotated in TMDS and again in AHLTA when the patient has returned to the United States.

9. Efforts should be made in the future to standardize the type of RIVCF used at all combat theater locations.

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Documentation in Prolonged Field Care (CPG ID:72)

This CPG is meant to provide medical professionals who treat severely injured or sick patients in austere environments with recommendations for documentation that will allow them and subsequent providers along the evacuation chain to optimally manage complex, often unstable casualties.

INTRODUCTION

This Role 1, prolonged field care (PFC) Clinical Practice Guideline (CPG) is intended to be used after Tactical Combat Casualty Care (TCCC) guidelines when evacuation to higher level of care is not immediately possible. A provider of PFC must first and foremost be an expert in TCCC. This CPG is meant to provide medical professionals who treat severely injured or sick patients in austere environments with recommendations for documentation that will allow them and subsequent providers along the evacuation chain to optimally manage complex, often unstable casualties. Recommendations follow a "minimum," "better," "best" format that provides alternate methods when optimal hospital options are unavailable.

BACKGROUND

PFC frequently involves the care of complicated, critically injured or sick casualties who are normally managed in medical treatment facilities. For patients that survive the initial trauma or sickness, the biggest risk of death is from circulatory shock and its complications. All severely injured and sick patients must be closely monitored for signs of shock and decompensation because the best treatment for shock is early recognition, treatment of the cause, and resuscitation. One method used by intensive care units to monitor critical patients is trending vital signs, physical exams, and fluid outputs recorded on a flowsheet that facilitates recognition of changes that could mark the early signs of decompensation.

In the PFC environment, one of the few techniques available to the medical provider that is identical to those used in hospitals is documentation of key clinical trends. It is critical that Medics are trained on the interpretation of clinical trends. It is also essential that Medics cross-train nonmedical teammates to take and record vital signs, outputs, key exam findings, and interventions to free the medic to do other tasks as well as to sleep if care of the casualty is especially prolonged.

Documentation that can help the medic and successive caregivers manage complicated patients includes:

- TCCC Card, DD1380
- PFC flowsheet
- Telemedicine guide
- Handoff report

Finally, completion of the PFC after-action report (AAR) will contribute greatly to performance improvement to develop training, tools, and techniques for improving the care of casualties in austere environments.

PATIENT DEMOGRAPHICS

While some casualties will be unable to provide name, identification number, date of birth (DOB), or other identifying information, every effort should be made to collect and document this information in order to facilitate the inclusion of prehospital documentation into the patient's medical record. This information not only helps the longitudinal care of casualties as they progress through the evacuation chain, it also provides the vital link to connect prehospital treatments delivered to survival and long-term outcomes in order to guide recommendations for improving trauma care.

***NOTE**: Medical treatment facilities use pseudo names assigned when a patient's real name is unknown. In such cases, every effort should be made to continue the same pseudo name through transfers of care. Prehospital documentation submitted after patient transfer, to include AARs, should use the same name or pseudo name assigned at the first treating MTF.*

DOCUMENTATION OF PREHOSPITAL CARE

GOALS

- Transmit important medical information to the next level of care
- Permanently record information vital to service members injured in combat
- Contribute to performance improvement in prehospital care.

Minimum: TCCC Card DD1380

- The DD1380 is organized as a MIST (Mechanism, Injuries, Signs and Symptoms, Treatments) report (Appendix A).
- Note the time casualty is received and include time of injury (if known and different from when received) and time of all key interventions (e.g., tourniquet, blood transfusion, tranexamic acid [TXA] dosing).
- List injuries and annotate on the diagram. Tourniquets and tourniquet times are also annotated on the diagram.
- Vital signs, including mental status AVPU (alert or responsive to voice, pain, or unresponsive) and pain scale, should be recorded to the greatest extent possible—up to four sets of vital signs can be recorded on the TCCC card.
- Document treatments to include external hemorrhage control, airway, breathing, fluids, medications, and other interventions on the reverse side of the TCCC card.

Better: PFC Flowsheet

As a follow-on to the TCCC card, the PFC flowsheet is used to document trends over time and is the most useful tool to recognize important clinical changes in complex casualties such as decompensation, response to resuscitation, development of complications, effectiveness of medications, etc. The PFC flowsheet is one of the most effective ways to improve the level of care provided in PFC situations.

- When prehospital care transitions to PFC, documentation should transition from the TCCC card to the PFC flowsheet. There is no exact time for this transition to occur; however, once all of the available time blocks on the TCCC card are filled and evacuation to higher level of care is not imminent, then documentation can transition to the PFC flowsheet (Appendix B).
- The PFC flowsheet not only serves to document care and identify trends but also contains a checklist of interventions that may be needed through the included patient care and nursing care checklists. Such checklists can greatly aid task-saturated, fatigued Medics by providing a quick point of reference for important tasks that should be performed regularly to improve care and reduce the risk of complications to their patients.

- The PFC flowsheet also includes:
  - Vital signs
  - Fluid input and output
  - Medication times, route, dose
  - Physical exam findings
  - Problem list
  - Treatment plan
  - Telemedicine call script

Best: AAR

- An AAR should be completed after patient handoff. In addition to the TCCC card and PFC flowsheet, a structured AAR is used to collect lessons learned and improve care. In cases where documentation is not able to be completed before patient handoff or was lost after handoff, the AAR can also serve as a supplement to the medical record.
- TCCC and PFC AARs are available at https://jts.health.mil/index.cfm/PI_CPGs/cpgs
- TCCC or PFC AARs, along with any medical documentation not completed before patient handoff, should be completed within 24 hours of patient handoff and summited to the Joint Trauma System (JTS) prehospital organizational email box: dha.jbsa.healthcare-ops.list.jts-prehospital@health.mil
- The unclassified medical AAR should be accomplished in addition to unit-required classified AARs.

TELEMEDICINE GUIDE

GOAL

Goal: Facilitate communication between prehospital provider and telemedicine consultant.

Rehearsal of telemedicine consultation between prehospital providers and remote physician consultants has shown that communication is optimized when the caller completes a telemedicine guide or script before calling the consultant and uses it during the consultation. In addition to transmit- ting medical information to the consultant, it is important for the caller to provide information about the care context and a summary of capabilities currently available. An image of the casualty and an image of the care environment are helpful for remote consultants to understand the operational constraints faced by the local caregiver. Capabilities that are important to convey to remote consultants may include the training level of the provider, available medications, medical supplies, monitoring, ultrasound, etc. Reading or sending a photograph of a written capabilities list will more quickly orient the consultant to the operational environment of the caller and reduce time spent asking the caller for items that are not available. If urgent teleconsultation is needed, do not delay calling to fill out a guide sheet or send e-mails. For additional details, see Teleconsultation in prolonged field care position paper.[1]

Minimum: Read from TCCC card.

Better: Use telemedicine report incorporated in the PFC flowsheet.

Best: Use the Virtual Critical Care Consultation guide (Appendix C) and send a picture of casualty, capabilities, and vital sign trends to the consultant via email or text using appropriate operational security and protections of patient privacy.

HANDOFF REPORT

GOAL

Goal: Ensure safe transition to the next level of care.

Adverse events may occur due to poor handover of a patient from one level of care to another. The PFC provider's job is not done until the receiving team understands the patient's condition and can begin to manage the patient appropriately.

Summarize in organized format:

1. Overall condition of the patient: stable or unstable; better, same, or worse.
2. Mechanism of injury or illness
3. Injury(ies), current physical exam
4. Vital signs to include trends and urine output
5. Treatments (procedures, dressings, airway management, fluids, blood products, medications)

Minimum: Written handoff report that follows the MIST format (e.g., TCCC Card).

Better: Add the PFC flowsheet.

Best: Add a dedicated handoff sheet (e.g., SBAR handoff report2, PFC handoff report3).

ELECTRONIC DOCUMENTATION

Electronic documentation is the standard in hospitals and advanced field medical facilities. Devices such as the Tempus Pro (Remote Diagnostic Technologies LTD, United Kingdom) and BATDOK (USAF, 711 Human Performance Wing, OH) are devices designed for the operational environment that can compile detailed patient records that support many of the recommendations in this CPG. These and other similar devices and applications may improve the accuracy of patient records, reduce the burden of data entry for the prehospital provider, and provide other features to improve patient care such as critical value alarms and telemedicine communication. Where such devices are fielded and supported with network connectivity, their use for austere PFC environments is encouraged.

JTS hosts a variety of fillable forms at https://jts.health.mil/index.cfm/documents/forms_after_action

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Documentation Requirements for Combat Casualty Care (CPG ID: 11)

This CPG stresses the need for complete and accurate trauma documentation of an event, including evacuation on all trauma patients from point of injury to Role 2/3.

BACKGROUND

Trauma documentation within the military trauma system supports optimal patient care and performance improvement (PI). Documentation has continuously increased since the Joint Theater Trauma Registry (JTTR), now known as the DoD Trauma Registry (DoDTR), was initiated in 2004. DoDTR data acquisition and processing has improved greatly, due in part to standardization of the Resuscitation Record, Tactical Combat Casualty Card (TCCC), and Tactical Evacuation (TACEVAC) Patient Care Record (PCR) as well as standardized prehospital and en route care after action reports (AARs) and PI reviews. The dedicated efforts by Service, Combatant Command, and JTS personnel to capture these documents following patient care promotes inclusion within the medical record and transfer to the DoDTR. During massive casualty events, documentation reduces chaos and improves patient tracking.

Accurate documentation improves:

- Trauma readiness
- Treatments
- Outcomes
- Standard of care development
- The evaluation of rescue systems
- Casualty response processes
- Adherence to approved treatment guidelines

It is critical that all levels of the trauma system, including point of injury, en route, austere and facility-based roles of care, ensure that their casualty documentation, after action reports, and PI forms reach the JTS for incorporation into the DoDTR.

Combat casualty care documentation incorporates information from numerous sources such as nursing flow sheets, monitors, Medical Evacuation (MEDEVAC) patient care records, point of care laboratory devices, and anesthesia records. Documentation of history, physical examination, interventions and decision-making not only optimizes ongoing care of the casualty, but also contributes to improved care of future casualties when incorporated into the DoDTR. For prehospital providers and small teams who operate in a kinetic and austere setting, it may not be possible to document and provide care simultaneously, and providing optimal care always takes priority. In such cases, completion of the documentation and AAR as soon as possible after the event with transmission to JTS, preferably within 72 hours of injury, is necessary and meets the intent of this CPG.

Documentation of trauma care provided to all patients treated within the military system is relevant, and all categories of patients treated are incorporated into the DoDTR. It is critical that all roles of care utilize the same name for an individual casualty according to the theater standard pseudo name policy to ensure quality data. This requires communication and follow up, particularly for reports submitted after evacuation from that role of care. While technology is being implemented to facilitate electronic documentation by the initial roles of care, much of the initial trauma documentation is still hand-written and must be scanned in to the Theater Medical Data Store (TMDS) order to incorporate into the records. As there is no global solution to this challenge, each treating location must identify a means to transfer hand-written records to a location where they can be scanned.

PATIENT CARE DOCUMENTATION GUIDELINES

PREHOSPITAL DOCUMENTATION

The DD 1380, TCCC Card, is initiated by point of injury non-medical or medical personnel once all major life threats have been addressed in accordance with TCCC guidelines. Each Service member should carry a DD 1380 with their personal identifiers pre-positioned and stored within their first aid kit.

The purpose of the DD 1380 is to provide prehospital providers a standardized document to record all TCCC interventions administered at the point of injury and facilitate handoff to the next role of care. It should accompany the casualty during initial evacuation and be accounted for upon arrival at the first surgery capability. The TCCC card will be scanned and uploaded into TMDS utilizing the casualty name established by the first surgical team.

TCCC AAR documents should be submitted for each casualty to the JTS via the AAR submission email link on the JTS Forms and After Action Report Submission web page within 72 hours post injury or as soon as possible after mission completion. AARs must be submitted using the actual name or pseudo name for all patients subsequently treated by surgical teams; this requires communication and follow up between the prehospital and surgical teams. A secure email option is provided for convenience, however AARs submitted to the DoDTR should include only content up to the "For Official Use Only" level. The prehospital PI form should be used to review care and documentation and should be completed by the Unit Medical Officer or the Senior Enlisted Medical Advisor and submitted along with the AAR using the previous JTS web link. Units requesting a unit-specific PI report can contact JTS at dha.jbsa.healthcare-ops.list.jts-prehospital@health.mil (unit must be identified on the AARs or a patient log provided).

When prehospital care transitions to PFC, documentation should transition from the TCCC card to the Prolonged Field Care (PFC) Worksheet. As a follow-on to the TCCC card, the PFC Worksheet is used to document trends over time and is the most useful tool to recognize important clinical changes in complex casualties such as decompensation, response to resuscitation, development of complications, effectiveness of medications, etc.

TRANSPORT DOCUMENTATION

The TACEVAC Evacuation Patient Care Record (DA 4700) and AAR should be initiated on all patients transported via ground or rotary-wing platform. This form may be initiated during transport, but is ideally suited to be completed electronically after mission completion. Forms should be reviewed by local medical directors to aid in unit level quality assurance efforts. These forms should be completed within 72 hours of a patient care event, and may be completed digitally or by hand. (This form is not intended to supersede the AF 3899 during patient transport by Air Force air evacuation assets).

ROLE 2 & ROLE 3 DOCUMENTATION

A Resuscitation Record (DD 3019) and any required supplemental documentation (JTS Burn Flow Sheet, C-Spine Clearance Form, etc.) should be initiated on ALL patients anticipated to be admitted in a Role 2 setting or higher role of care (including those patients who are transferred for admission to a host nation facility). This includes patients with battle/non-battle injury who are coalition forces, local nationals, contractors, and civilians. *It is the intent of this guideline that the broadest definition of* ***trauma*** *be used.* This should include the majority of patients with single or multi-system injury seen in the emergency department who may require admission or who are admitted directly to the hospital, and is to be used as the primary method of initial documentation.

In situations when there are not enough team members to allocate one individual to documentation, such as during mass casualty events or austere surgical team treatments, the MASCAL/Austere Team Record may be utilized (DD Form # pending).

The Resuscitation Record (DD 3019) should be completed on all patients evaluated and admitted within the first 72 hours following injury, including but not limited to the following injury causes:

- Building Collapse
- Bullet/Gunshot Wound/Firearm
- Burn
- Explosively Formed Projectile/Penetrator
- Fall
- Fire/Flame
- Improvised Explosive Device
- Inhalation Injury
- Mine
- Mortar/Rocket/Artillery Shell
- Multi-Frag
- Motor Vehicle Crash
- Sports
- Unexploded Ordnance
- All trauma admissions to any/all Role 2 or 3 facilities in the continuum

All care delivered by each resuscitation and surgical capability will be documented for that role of care on the appropriate record and signed by the physician (preferably), nurse, or team member documenting before transport to next role of care. In situations where evacuation occurs before documentation can be completed, the record should be completed as soon as possible and transmitted electronically to the next role of care as well as to JTS. It is important that all documents are annotated with provider names with both a time and date of injury as well as arrival to surgical capability in order to ensure timeline accuracy within the registry. If time of injury is an estimate, note that in the documentation.

THEATER MEDICAL DATA STORE & TRAUMA LOGS

The TMDS provides web-based access to Service member medical information entered at deployed medical treatment facilities using AHLTA-Theater (Armed Forces Health Longitudinal Technology Application), Shipboard Automated Medical System (SAMS), Global Expeditionary Medical System (GEMS), Caché TC2, and TRANSCOM Regulating and Command & Control Evacuation System (TRAC2ES). Additionally, all documentation saved as PDF files, including scanned documents, can be uploaded to TMDS as PDF files.

Authorized individuals may request a TMDS user account by accessing the website https://tmds.tmip.osd.mil, connecting to "need access" and completing the registration form; account requests must be reviewed and validated before user accounts are created. User accounts are usually validated and activated within 48 hours of the request. TMDS is accessible from a government computer with .mil account.

Records entered in the deployed electronic health records must utilize an appropriate ICD-10 diagnosis code to ensure the records are identified as trauma records (do not utilize the generic 9999 code). In order to ensure all TMDS trauma records are identified by JTS, each team must record a log of trauma patients treated and submit the log to JTS weekly. The log should include the following for each patient:

- Name/pseudo name; SSN/PSSN
- Patient Category; Injury Date; Transferred From (prior to arrival)
- Arrival Date; Discharge Date
- Discharge Status

- Discharge/Transfer To
- Record uploaded in TMDS/Sent to JTS? (YES/NO)

In the event that no trauma patients were treated the previous week, a 0-patient report should be submitted. Submit to: dha.jbsa.healthcare-ops.list.jts-trauma-log@health.mil

Services should develop and implement doctrine, tactics, training, security procedures, and logistical support that ensures combat casualty care documentation is uploaded into TMDS and transmitted to the JTS.

DOD & JTS FORMS

Fillable PDF forms are available on the ***JTS Forms and After Action Report Submission*** website. Forms can be downloaded individually or together in the forms ZIP file at https://jts.health.mil/index.cfm/documents/forms_after_action

PRIMARY REQUIRED FORMS

- Tactical Combat Casualty Care Card (DD 1380)
- Point of Injury Tactical Combat Casualty Care After Action Report
- Tactical Evacuation After Action Report & Patient Care Record and Instructions
- Resuscitation Record (DD 3019) and Instructions
- Mass Casualty (MASCAL)/Austere Trauma Team Resuscitation Record and Instructions

PROLONGED FIELD CARE

- Prolonged Field Care Casualty Card - Worksheet
- Excel version of Prolonged Field Care Card - Worksheet

BLOOD TRANSFUSION FORMS

- Vampire Program CCOP-01: Urgent Resuscitation Using Blood Products During Tactical Evacuation From Point Of Injury
- Urgent Resuscitation Using Blood Products During Tactical Evac - Appendix A
- Infectious Disease Testing for Blood Donation (ASBP 145)
- Eldon Card ABO/Rh Typing Record (ASBP 147)
- Pre-screen Whole Blood Sample Shipping Manifest (ASBP 148)
- Emergency Release Letter of Understanding (tested) (ASBP 150A)
- Emergency Release Letter of Understanding (untested) (ASBP 150B)
- Whole Blood Transfusion Checklist (ASBP 151)
- Blood or Blood Component Transfusion Record ASBP (SF 518)
- Emergency Whole Blood Donation Record (ASBP 572)

- AABB Medications Deferral List
- DHQ Medication Deferral List

BURN CPG FORMS

- JTS Burn Resuscitation Worksheet
- JTS Burn Resuscitation Flow Chart
- Lund Browder Burn Estimate Diagram (Adult & Pediatric)
- JTS Burn CPG Physician's Order Form

REBOA FORM

- Aortic Occlusion (AO) Procedure Notes: REBOA or Resuscitative Thoracotomy

SPINAL INJURY – CERVICAL & THORACOLUMBAR FORMS

- Cervical Spine Clearance Status Note
- ASIA Worksheet for Spinal Cord Injury
- Combat Neuro Exam Worksheet

BRAIN INJURY FORM

- Military Acute Concussion Evaluation 2 (MACE 2) Form, 2018

MILITARY WORKING DOG FORMS

- Canine Tactical Combat Casualty Card (DD 3073) and Instructions
- Canine Treatment and Resuscitation Record (DD 3074) and Instructions

All forms can be downloaded from the JTS website:

JTS Forms and AARs: https://jts.health.mil/index.cfm/documents/forms_after_action

EXPECTATIONS : FORM COMPLETION

- All individuals providing prehospital trauma care will complete a DD 1380 TCCC Card and ensure it is passed to providers at the next role of care for all casualties treated. The TCCC AAR form will be completed by the point of injury provider and submitted within 72 hours after mission completion via the JTS AAR Report Submission site at: https://jts.health.mil/index.cfm/documents/forms_after_action. The Prehospital PI Form will be completed by the unit senior medic or Command Surgeon and submitted to the JTS TCCC/POI AAR email submission link.
- All individuals providing en route care during MEDEVAC or Casualty evacuation (CASEVAC) by air or ground will complete a TACEVAC AAR & PCR or Service equivalent form and submit within 72 hours after mission completion to the JTS AAR Report Submission site at: https://jts.health.mil/index.cfm/documents/forms_after_action. The TACEVAC Form will be

completed by the unit senior medic or Command Surgeon and submitted via the JTS TACEVAC AAR & PCR submission email. .

- Air Evacuation and Critical Care Air Transport teams will use appropriate Air Force documentation forms (e.g., AF 3899 series) and submit forms to JTS within 7 days after mission completion. dha.jbsa.healthcare-ops.list.jts-trauma-registry@health.mil.
- All Role 2 and Role 3 surgical teams and all austere resuscitative and surgical teams will complete the DD 3019 Resuscitation Record or MASCAL/Austere Trauma Team Record (whichever is most appropriate) for all trauma patients anticipated to be admitted and ensure the document is uploaded into TMDS within 72 hours of injury.
  - The DD 3019 Resuscitation Record is considered the primary form and should be used preferentially for trauma evaluations.
  - The MASCAL form should be used in austere trauma scenarios and during mass casualty events when an individual cannot be dedicated to documentation. The MASCAL form is not a substitution for the DD 3019 Resuscitation Record.

***NOTE**: Any documentation related to patient care should be uploaded to TMDS. **Documentation of trauma care does NOT require a DD/DA/AF form number to be uploaded to the medical record and should never be discarded.** Examples may include: photos of the injury and surgical procedures; photos of medical documentation written directly on the skin or dressings. All documents detailed in this CPG should be included, as well as any other medical form used that is not listed within the CPG (i.e. medication administration record, anesthesia record, SF 600).*

PI MONITORING

POPULATION OF INTEREST

All trauma patients evaluated within 72 hours of injury and admitted to Role 2 or Role 3.

INTENT (EXPECTED OUTCOMES)

1. All trauma patients who receive prehospital care have a DD 1380 TCCC card completed in patient's record and uploaded in TMDS.
2. All patients evacuated by MEDEVAC or CASEVAC air or ground have a DA 4700 form completed in patient's record and uploaded in TMDS.
3. Trauma log is received at least monthly from all Role 2 and Role 3 locations.
4. Resuscitation Record is completed at each surgical role of care on all trauma patients who present within the first 72 hours following injury and are admitted.
5. Resuscitation Record Part 1 has time of injury and time of arrival documented.
6. Resuscitation Record has complete and accurate documentation of patient identification utilizing theater trauma naming convention policy.
7. Resuscitation Record Part 2 has complete history and physical documented.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients who have a DD 1380 TCCC card and/or TCCC AAR uploaded in TMDS or submitted to JTS.
2. Number and percentage of patients evacuated by MEDEVAC or CASEVAC air or ground who have a DA 4700 form uploaded in TMDS or submitted to JTS.
3. Number and percentage of Role 2s that submit a trauma log to JTS each month.
4. Number and percentage of patients of in the population of interest with Resuscitation Record uploaded into TMDS or received by JTS within 72 hours of injury.
5. Number and percentage of patients in population of interest with time of injury and time of arrival documented in Resuscitation Record Part 1.
6. Number and percentage of patients in population of interest with complete and accurate patient identification documented according to theater trauma naming convention policy.
7. Number and percentage of patients in population of interest with complete history and physical documented.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed biannually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

1. It is the trauma team leader's responsibility to ensure the Resuscitation Record Part 2, Physician H&P is complete at Role 2 and Role 3.
2. It is the responsibility of the nurse assigned to the trauma bay/patient to ensure the Resuscitation Record Part 1, Nursing Flow Sheet is completed at Role 3.
3. A member of the trauma team who is receiving report (Critical Care Air Transport, MEDEVAC, ground ambulance) should request a copy of the transport run-sheet and ensure it is included in the patient's record. All times on the Resuscitation Record should be local 24-hour military format (hhmm).

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Drowning Management (CPG ID:64)

This guide helps first responders, prehospital emergency medical service personnel, and medical department personnel evaluate, diagnose and manage common in-water pathologies.

GOALS

This CPG provides an overview of drowning and associated conditions based on the best available current medical evidence. It should be used as a standardized framework to guide first responders, prehospital emergency medical service personnel, and medical department personnel in evaluating, diagnosing, and managing common in-water pathologies.

EPIDEMIOLOGY OF DROWNING

- Highly skilled swimmers and aquatically adaptable service members such as U.S. Navy Divers, EOD technicians, and SEALs die every year from drowning.
- Responsible for > 500,000 civilian deaths/year worldwide (thought to be greatly underestimated) boating accidents and natural disasters (floods, tsunami, etc.).
- Leading cause of death worldwide in boys aged 5-14 (2nd most common cause in children, 3rd in most common cause young adults).
- Alcohol is involved in the majority of drowning accidents.
- Leading cause of deaths or contributing factor among scuba divers (100-150/year). In many cases it is difficult to determine if drowning is the primary cause or secondary to an in water emergency such as (1) loss of buoyancy control; (2) entanglement; (3) air supply exhaustion; or (4) medical condition (MI/hypoglycemia/seizure).[1-3]

PATHOPHYSIOLOGY OF DROWNING

Immersion in water, panic, overexertion/exhaustion, inability to cope with rough water, or effects of hypo/hyperthermia lead to:[1-5]

- Airway below the surface → breath hold breakpoint (inability to resist urge to breath) → hypoventilation → hypercapnia, respiratory acidosis, and hypoxemia → loss of consciousness (LOC) → passive flooding of the airway → cardiopulmonary arrest
- Cold water immersion – water conducts heat 25x faster than air resulting in a rapid drop in core temperature.
  - Shock to system causing sudden gasp for air, tachypnea, vasoconstriction, tachycardia.
  - May progress to arrhythmias, altered mental status, diminished strength and coordination.

PREVENTION

Respect the power of moving water and debilitating effects of cold water on the body.[1,6,7] Fast moving water should be treated with the same respect as a 1,000 foot cliff.

- Wear a personal flotation device (PFD) and have a PFD available for every person.[1,6,8]
  - Huddle - if in a group, everyone face inward and huddle with arms interlocked.
  - Get as much of body out of the water as possible (climb onto submerged boat), wind removes less heat than water.[1,6,9]

- Learn to swim, tread water, or float (not a substitute for PFD) and always swim with others.
- Have a well-developed safety and rescue plan that is exercised and practiced routinely.[1,6]
- Average vehicle takes 30 seconds to 2 minutes to sink.
- Once even partially submerged, windows and doors become impossible to open or kick out (unlike what is commonly seen in the moves). Do not wait, act immediately to escape.
- Vehicle escape procedure:
    1. Unfasten adult restraints.
    2. Open windows.
    3. Unfasten child restraints.
    4. Children exit youngest to oldest (if multiple children have oldest go first and hold onto vehicle and pass younger children out by the adult still inside the vehicle).[1,6,7,10]

PHASES OF TREATMENT[1,6]

1. Rescue and In-water Resuscitation
2. Initial Resuscitation on Land
3. Advanced Prehospital Care
4. ER/ICU Care

COLD WATER IMMERSION SELF AID

Sudden immersion in cold water (< 91.4°F/33 °C) causes panic and reflexive gasp for air and rapid breathing making: [1,2,5-7,9,11,12]

- Inhalation/aspiration of water more likely.
- Core temperature drop causing arrhythmias, confusion, incapacitation (diminished strength and coordination) increasing the chance of drowning.
- Water conduct heat away from the body 25 times faster than air leading to immersion hypothermia – impaired meaningful movement usually precedes.[1,6,11]
- 1 min/10 min/ 1 hour /2 hour Rule 1,3 – steps to survival:
    1. Control your breathing and survive the first minute.
    2. You have 10 minutes to move thoughtfully and carefully before you will become incapacitated by cold.
    3. You have 1 hour before you will become unresponsive due to hypothermia.
    4. You have 2 hours before your heart stops beating.
    5. Assuming you have a floatation device, while awaiting rescue assume HELP (heat escape lessening posture) by bring your knees to your chest and cross your arms over them or Huddle position by grouping together. [1,6,7,9,17]

Figure 1. Ice rescue training

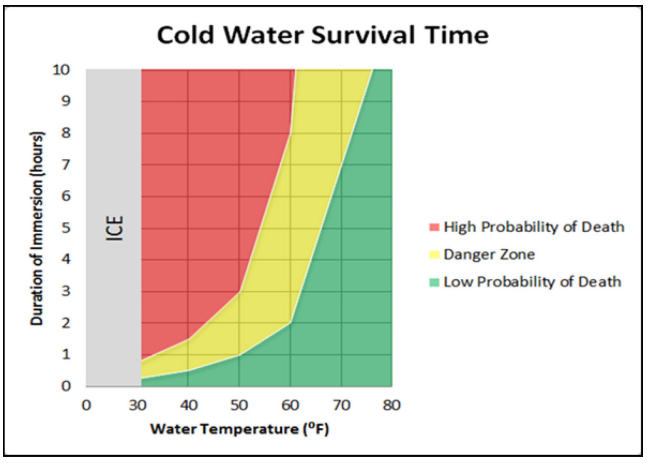
Graphic created by LT Parenteau from USCG video[13] available at https://www.youtube.com/watch?v=UzHC8hNLp34

Table 1. Expected Survival Time in Cold Water

Water Temperature	Time to Exhaustion or Unconsciousness	Expected Survival Time
> 80° F (27° C)	Indefinite	Indefinite
70–80° F (21–27° C)	3–12 hours	3 hours – indefinitely
60–70° F (16–21° C)	2–7 hours	2–40 hours
50–60° F (10–16° C)	1–2 hours	1–6 hours
40–50° F (4–10° C)	30–60 minutes	1–3 hours
32.5–40° F (0–4° C)	15–30 minutes	30–90 minutes
<32° F (<0° C)	Under 15 minutes	Under 15–45 minutes

Based off of table available here: http://www.ussartf.org

Figure 2. Cold Water Survival Time



Graph created by LT Parenteau based on data in table.9

RESCUE AND IN-WATER RESUSCITATION

1. Identify and locate the victim (ask if there are more than one).[1,6]
   - Often seen motionless, sinking slightly below the surface.
   - Diving into the water and never surfacing.
2. Goals: initially type of water does NOT matter (salt, fresh, clean, dirty).[1,6]
   - Alert advanced life support as soon as possible.
   - Accurately record environmental conditions including time of submersion, type and temperature of water and air, scuba diver (depth, time at depth, type of dive rig).
   - Rescuer safety is a priority (avoids more casualties). Rescuers must balance personal safety and removing the drowning victims from the water by the fastest means available by using methods like reach, throw, row, tow, go:[1,6,14]
     1) Reach with an object from the safety of the shore or ship.
     2) Throw an object like a rope or flotation devices (this may help the victim stay afloat or the search and rescue team locate the victim.)
     3) Row (or paddle) a smaller craft to the victim if they are too far from shore to reach or have a floatation device thrown. The rescuer should ideally stay out of the water.
     4) Tow them into shore or away from danger in the water (i.e. swift water rescue).
     5) Go into the water (as a last resort) to rescue the victim (highest risk to rescuer).
   - Additional risks to the rescuer include open water, swift water, or ice.
   - In water rescue breaths should only be done when rapid extraction is NOT feasible. In water chest compressions are NOT effective.[1,3,15,16]
   - Cervical spine injury in drowning victims is low (0.009%). Unnecessary cervical spine immobilization can impede delay delivery of rescue breaths and adequate opening of the airway. Routine stabilization of the cervical spine in the absence of circumstances that suggest a spinal injury (diving, boat accident, and fall from height) is not recommended. If suspected, protect cervical spine by assuming neck injury (use jaw thrust to open the airway).[1, 4, 6,7,12]
   - Handle patients rescued from cold water gently as possible as rough handling of hypothermic patients may trigger a lethal arrhythmia. Priority remains oxygenation, ventilation, and restoring circulation.

Figure 3. HELP posture

Pictures modified by LT Parenteau [8,17]

INITIAL RESUSCITATION ON LAND [1,3,6,7,12]

1. Call for help and encourage patient to move away from danger. [15,16]
2. Place the patient parallel to the shoreline so that the head and feet are at the same level.
3. CPR: Airway, Breathing, Circulation (not CAB due to respiratory impact of drowning)
    - If unconscious and not breathing, begin with 5 rescue breaths (ABC rather than CAB), then continue with 30:2 (compressions: rescue breaths). Five breaths are used initially because water in the airways can interfere with effective alveolar expansion initially. A drowning patient with only respiratory arrest usually responds after a few rescue breaths.
    - Cardiac arrest from drowning is due primarily to lack of oxygen.
4. Ventilation support with available tools (oxygen, bag valve mask (BVM), etc.)
5. Prepare for vomiting: 65% of victims requiring rescue breathing vomit; 88% of those receiving chest compressions will vomit.

WHO TO EVALUATE [1,3,6]

- Anyone who required resuscitation : All victims of drowning who require any form of resuscitation (including rescue breathing alone) should be transported to the hospital for evaluation and monitoring, even if they appear to be alert and demonstrate effective cardiorespiratory function at the scene
- Anyone unresponsive in the water
- Anyone exhibiting distress (shortness of breath, persistent cough, anxiety, tachypnea, syncope, foam in the mouth or nose, change in vital signs, abnormal breath sounds, or hypotension).

ADVANCED PREHOSPITAL CARE

Secure airway → improve oxygenation → stabilize circulation → gastric decompression → thermal insulation.[1,6]

Maintain airway, begin CPR if necessary.

1. Attempt resuscitation unless clear signs of death (dismemberment, rigor mortis, decomposition, decapitation, etc.) or operational requirement.[4]
    - Rare case reports surviving prolonged submersion (especially in ice water).
    - Pulse may be difficult to identify due to hypothermia or hypotension. Do not use as sole indicator of death.
2. Avoid head down positioning or abdominal thrusts as they delay ventilation and increase vomiting, which increases the risk of aspiration and mortality. Heimlich maneuver NO LONGER recommended for drowning.[7,14,18]
3. If unconscious but breathing, stabilize airway by putting patient in recovery (lateral recumbent) position as vomiting is common and can lead to aspiration.[1,3]
4. If unconscious and not breathing, begin with 5 rescue breaths (ABC rather than CAB), then continue with 30:2 (compressions: rescue breaths). Five breaths are used initially because water in the airways can interfere with effective alveolar expansion initially. A drowning patient with only respiratory arrest usually responds after a few rescue breaths.[3,18,19]
5. If no response, assume cardiac arrest.
6. Finger sweep if foreign body (sand, seaweed, etc.).

100% O2 at 15 liters/min as soon as possible and until discontinued by medical officer.[1,3]

1. Victim may be able to compensate for drowning insult by ↑ respiratory rate.
2. Consider early intubation/mechanical ventilation/ Positive end-expiratory pressure (PEEP) or Bilevel Positive Airway Pressure (BiPAP). Anticipate patient may vomit, so need to monitor for this and consider rapid sequence intubation (RSI) if available to minimize risk of aspiration
3. Goal arterial oxygen saturation 92-96%: Place pulse oximeter on ear lobe or forehead for more accurate readings due to vasoconstriction.[20,21]

CARDIAC INTERVENTIONS

- Most common dysrhythmias are asystole and pulseless electrical activity (PEA).[1,3,4]
- Many ACLS interventions are ineffective with low core body temperatures, including pacing, atropine, lidocaine and defibrillation. Antiarrhythmics should be withheld for core temperatures of < 30 °C (86 °F), with emphasis placed on chest compressions and ventilations to maintain perfusion.[18]
- Manage arrhythmia per ACLS protocols.

- If history of unobserved LOC think C-spine precautions, intoxication, arterial gas embolism (AGE) - if history and circumstances suggest it (e.g., scuba diver surfacing unconscious or with neuro complaint)[2] If AGE is suspected, begin notification of hyperbaric chamber team.
- Consider gastric decompression as many drowning patients swallow water prior to inhaling and between 60-80% will vomit at some point during recovery or resuscitation.
- Keep the victim warm (use core temperature instead of infrared devices.

NOTE: *A low range refrigerator thermometer may be necessary). Stabilize body temperature - dry and insulate the patient to prevent heat loss.* [1,20,21]

- **Mild hypothermia**: > 34°C (>93.2°F): passive rewarming (i.e. warm blankets and environment).
  - Moderate hypothermia:30-34°C (86-93.2°F): active external rewarming will be required when available (i.e. heating blankets, radiant heat, forced hot air, warmed IV fluids at 43°C (109°F) , warm water packs).
  - Severe hypothermia: < 30°C (86°F): active internal rewarming will be required when available (peritoneal lavage, esophageal rewarming tubes, cardiopulmonary bypass, extracorporeal circulation); consider extracorporeal membrane oxygenation.
  - Withhold ACLS medications until temperature >30°C (86°F).[14]
  - Glucose – maintain between 80-140 mg/dL for ventilated patients.
- **IV fluids**: Obtain access, place Foley when appropriate to monitor output.[1,3]
  1. If oxygenation does not correct hypotension, give IV crystalloid.
  2. Continue monitoring vital signs as drowning patients are often mildly intravascularly dehydrated. This combined with mechanical ventilation using PEEP can increase intrathoracic pressure and decrease central venous return.
  3. Provide sufficient resuscitation to stabilize vital signs as this will also allow inotropic and mechanical ventilation to improve tissue oxygenation.
  4. Careful fluid management is key as drowning victims are at high risk for pulmonary edema.
  5. For hypothermic patients, continue monitoring temperature and use warmed IV fluids at 43°C (109°F) to rewarm.[12]
- **Assess patient history & physical, vital signs**, determine Glasgow coma scale.
  - Lung injury may take up to 6 hours to present and may not be immediately present.
  - Monitor for wet lung sounds, productive cough, rapid shallow breaths, substernal burning, irregular/slow heart rate, altered consciousness.
- **Transport**: Evacuate if victim required resuscitation, was unresponsive in the water, or has dyspnea or other respiratory symptoms.
  - Full neurological recovery has occurred occasionally after prolonged submersion in both icy and warm water.

- Continue resuscitation and transported to higher level of care unless there are obvious signs of death.

- **Brain resuscitation**: The following have not shown benefit: No role for mannitol, diuretics, hypertonic saline (unless hyponatremic), mechanical hyperventilation, barbiturate coma, intracranial pressure monitoring.
- **Terminating resuscitation efforts in the field.**[1,7]
  - After 1 hour submerged in water rescue should transition to body recovery with appropriate medical examiner evaluation for foul play (longest submerged survival 66 min).
  - Resuscitation may be stopped after 30 minutes of CPR without return of spontaneous circulation if patient is not hypothermic.
  - If there is any uncertainty, continue resuscitation until patient is rewarmed to 30-34 °C/86-93 °F, then continue CPR until asystole has persisted for >20 minutes.
  - Lowest recorded survival with neurologic recovery was core temp of 56.6°F/13.7 °C. However, only 17% of patients who require resuscitation in the ED will have functional recovery with minimal neurologic impairment and the ability to independently perform activities of daily living. If no cardiac activity once re-warmed, stop.
  - Increased duration of submersion increases risk of death or severe neurologic impairment.[3]
    - 0-5 min – 10%
    - 6-10 min – 56%
    - 11-25 min – 88%
    - >25 min – nearly 100%

Table 2. Duration of cardiopulmonary resuscitation (CPR) in Cases of Drowning[3]

Duration of cardiopulmonary resuscitation (CPR) in Cases of Drowning	
CPR	**Recommendation**
When to initiate	• Patient with respiratory distress or respiratory arrest • Submerged for < 60 min with no obvious physical evidence of death (dismemberment, rigor mortis, decomposition, decapitation)
Continue until	• Signs of life reappear, rescuers are exhausted, or advanced-life-support team takes over, or scene becomes unsafe for rescuer; or
When to terminate	• After 30 minutes of high quality CPR without return of vital signs for a patient submerged in warm water (i.e. non-hypothermic) • After patient has been rewarmed to 30-33 °C/86-93 °F (if hypothermic) and asystole has persisted for >20 minutes for a patient submerged in cold water

ED/ICU CARE

- If not done in the field or in route: secure airway → improve oxygenation → stabilize circulation → gastric decompression → thermal insulation [1,3,7,25]
- Access mental status using Glasgow Coma Scale:
  - GCS > 13 → Clear cervical spine. Monitor O2 saturations, Observe for 4-6 hours.
    - Normal O2 saturation and lung examination → discharge home
    - O2 saturation < 95% or abnormal lung exam treat as though GCS ≤ 13
  - GCS ≤ 13 or O2 saturation < 95% → Clear cervical spine, monitor O2 saturation
    Give supplemental O2 to keep saturation ≥ 95% (non rebreather at 15L/min → CPAP (caution if vomiting is a concern) → intubate and ventilate with low TV (6 mL/kg), low PEEP 5-10 cm H2¬O (high PEEP may impair venous return resulting in hypotension), and volume ventilation (10 L/min).
- Otherwise, follow JTS CPG for Acute Respiratory Failure.[22]
- May require extracorporeal membrane oxygenation.
- Delay weaning from vent for 24 hours (even when gas exchange appears adequate - PaO2/ FiO2 ≥ 250).
- Surfactant washout will take 2-4 days of CPAP and PEEP to regenerate (unique to drowning and important in weaning from the vent).
- Inhaled albuterol and nebulized ipratropium for spasm
- Glucose – maintain between 80-140 mg/dL for ventilated patients.
- Special studies as indicated based on scenario.
  - CXR – regardless of patient's clinical appearance to be used as baseline.
  - EKG: Normothermic – asystole or cardiac arrest poor prognosis (follow standard protocols) Hypothermic – asystole and cardiac arrest should undergo prolonged aggressive resuscitation until normothermic or considered not viable.
  - Labs: complete blood count, comprehensive metabolic panel, glucose, Troponin I, PT/PTT, urinalysis, CK, urine myoglobin, urine drug screen, blood alcohol.
- Monitor:
  - Acid base status with arterial blood gas to determine:
    - Alveolar ventilation – acceptable PaCO2 and pH
    - Gas exchange – PaO2 > 60 mmHg on supplemental O2
    - Perfusion – no metabolic acidosis
    - Temperature with core temp (usually rectal)
    - Volume (BP, urine output, CVP, etc.). Initial resuscitation with crystalloid. Echo recommended prior to inotropic or vasopressors.
- Transfer to inpatient or ICU setting.

- Monitor for signs of infection (pulmonary or CNS), which may be due to bacteria, fungus, or ameba depending on water source. No role for prophylactic antibiotics to prevent pneumonia (incidence only 12 % of drowning cases) or steroids to reduce lung or neurologic injury; no need for routine cultures unless clinically indicated.
    - Pneumonia - fever, Gram stain and culture tracheal aspirates, respiratory status changes, chest radiographs. Increased risk while on vent.
    - Meningitis - neck stiffness, headache, change in mental status.
- Consider consults to critical care, trauma, neurosurgery, or hyperbaric medicine specialists.[23,24]
- Consider and treat precipitating factors of drowning: trauma, spinal cord injury, seizure, MI, arrhythmia, toxin, syncope or hypoglycemia.
- Monitor for sepsis, disseminated intravascular coagulation (DIC), and renal insufficiency/failure.
- CT head and neck: edema or loss of gray-white matter distinction strongly predicts poor outcome, but normal CT is of little prognostic value.
- POST-CPR CARE: consider 12-24 hours of therapeutic hypothermia in patients with return of spontaneous circulation (ROSC) to improve neurological outcomes similar to cardiac arrest.
    - Drowning victims with ROSC who remain comatose should NOT be actively rewarmed above 90-93°F/32-34°C.
    - Drowning victims with ROSC whose core temperature is ≥ 93°F/34°C should be cooled to 90-93°F/32-34°C as soon as possible.
- Cerebral O2 consumption decreases 5% for each reduction of 1°C within the range 37-20°C .

PULMONARY CONSIDERATIONS

- **Hypoxemia** – decreased levels of oxygen in the blood. This is the primary and most important physiologic insult due to impaired ventilation and gas exchange.[1-6,25]
    - Water in lungs washes out surfactant causing atelectasis (alveolar collapse), diminished gas transfer, ventilation perfusion mismatch, and hypoxia.
    - Non-cardiac pulmonary edema, may cause acute respiratory distress syndrome (ARDS) immediately or be delayed (even after normal CXR) necessitating observation for 4-6 hours.
    - Initially due to external water insult, then worsened by microvascular damage activating inflammatory cascade, which results in extravasation of fluid into alveoli worsening ventilation/perfusion (V/Q) mismatch.
    - Shunting –hypoxic pulmonary vasoconstriction increases pulmonary hypertension driving fluid into alveoli.
- **Hypercapnia** – increased levels of carbon dioxide in the blood resulting in acidosis most often due to breath holding or apnea.
- **Contaminated water** (petroleum, sewage, organic, mud, sand, etc.) – may increase lung injury and require bronchoalveolar lavage to cleanse. [1,6,11]

NEUROLOGIC CONSIDERATIONS

- Central Nervous System (CNS) is most susceptible organ to brief periods of hypoxemia and the major cause of morbidity/mortality.
- Full neurologic recovery rarely happens after: 10 min normothermic submersion or 40 min hypothermic submersion
- Full mentation (time dependent) → unconsciousness → complete brain death
- Highly metabolic areas of the brain are most susceptible – vascular end zones, gray matter, thalamus, hippocampus.

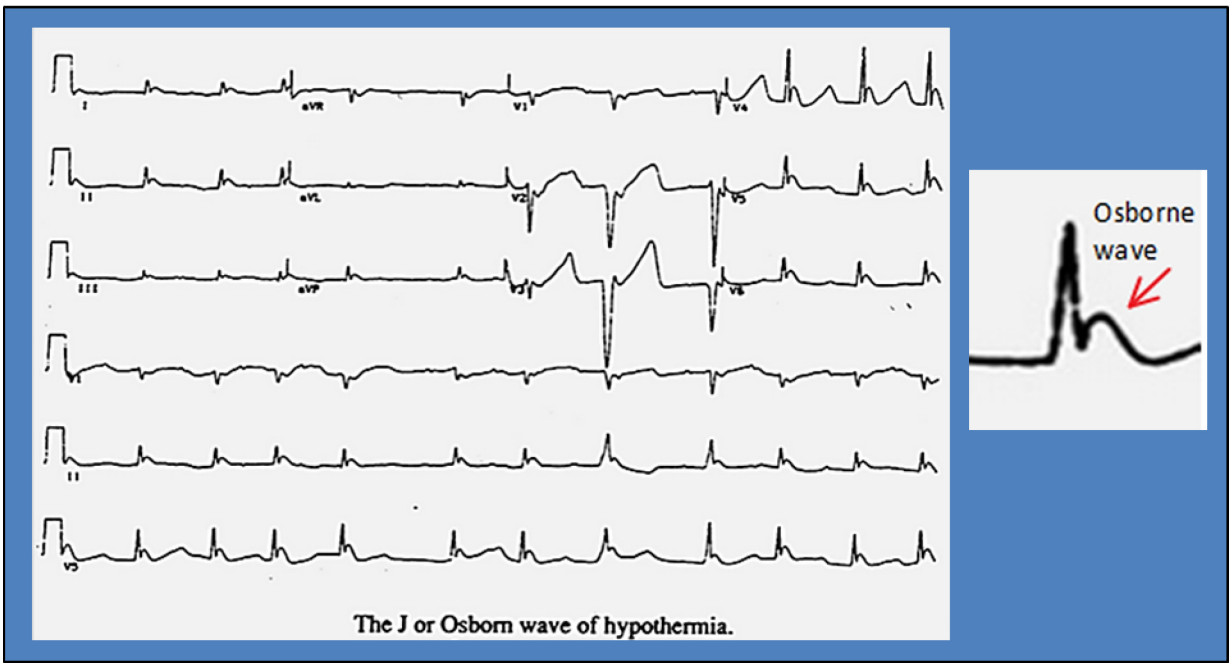
CARDIOVASCULAR CONSIDERATIONS

Major insult is hypoxemia and acidosis (two of the 5 ACLS "H's and T's") causing:

- Arrhythmias (most commonly): Tachycardia → Bradycardia → PEA → Asystole
- Ventricular fibrillation is not uncommon.
- Many ACLS interventions are ineffective with low core body temperatures, including pacing, atropine, lidocaine and defibrillation. Antiarrhythmics should be withheld for core temperatures of < 30 °C (86 °F), with emphasis placed on chest compressions and ventilations to maintain perfusion.[18]

If hypothermic, look for Osborne waves (extra deflection at the end of the QRS complex). See Figure 4.

Figure 4. EKG may demonstrate Osborn Waves (a small notch on the descending R-wave that is associated with hypothermia



HEMATOLOGIC & RENAL (ELECTROLYTE & METABOLIC) CONSIDERATIONS

- **Metabolic acidosis** – may progress from respiratory to metabolic and be severe.[1,4,5,3]
- **Electrolyte shifts** – no practical effects in humans (evidence of derangements was from old animal studies).
- **Hemolysis** – no practical effects in humans (evidence of DIC and hyperkalemia were from old animal studies).
- **Diving reflex** – massive vagal nerve stimulation from cold water immersion shunts blood to brain and cardiac tissue, away from skin/extremities/vascular beds and is coupled with bradycardia and decreased metabolic demand which sustains mean arterial pressure (MAP) with decreased cardiac output.[1,2,4,11]

SWIMMING INDUCED PULMONARY EDEMA (SIPE)

Most commonly presents in individuals conducting sustained strenuous surface swimming in cold water (i.e. NSW, Marine Combatant Divers, MARSOC Critical Skills Operators, Marine combat swimmers, special operators, scuba divers, and triathletes). SIPE is reported in 1.4% of triathletes and recurrence is not uncommon. Symptom severity can range from full recovery within 24 hours to death.

Risk Factors: hypertension, female, swimming ≥ 1.2 miles, prior history of SIPE

Diagnostic Criteria (during or immediately after exertional water immersion/swimming):

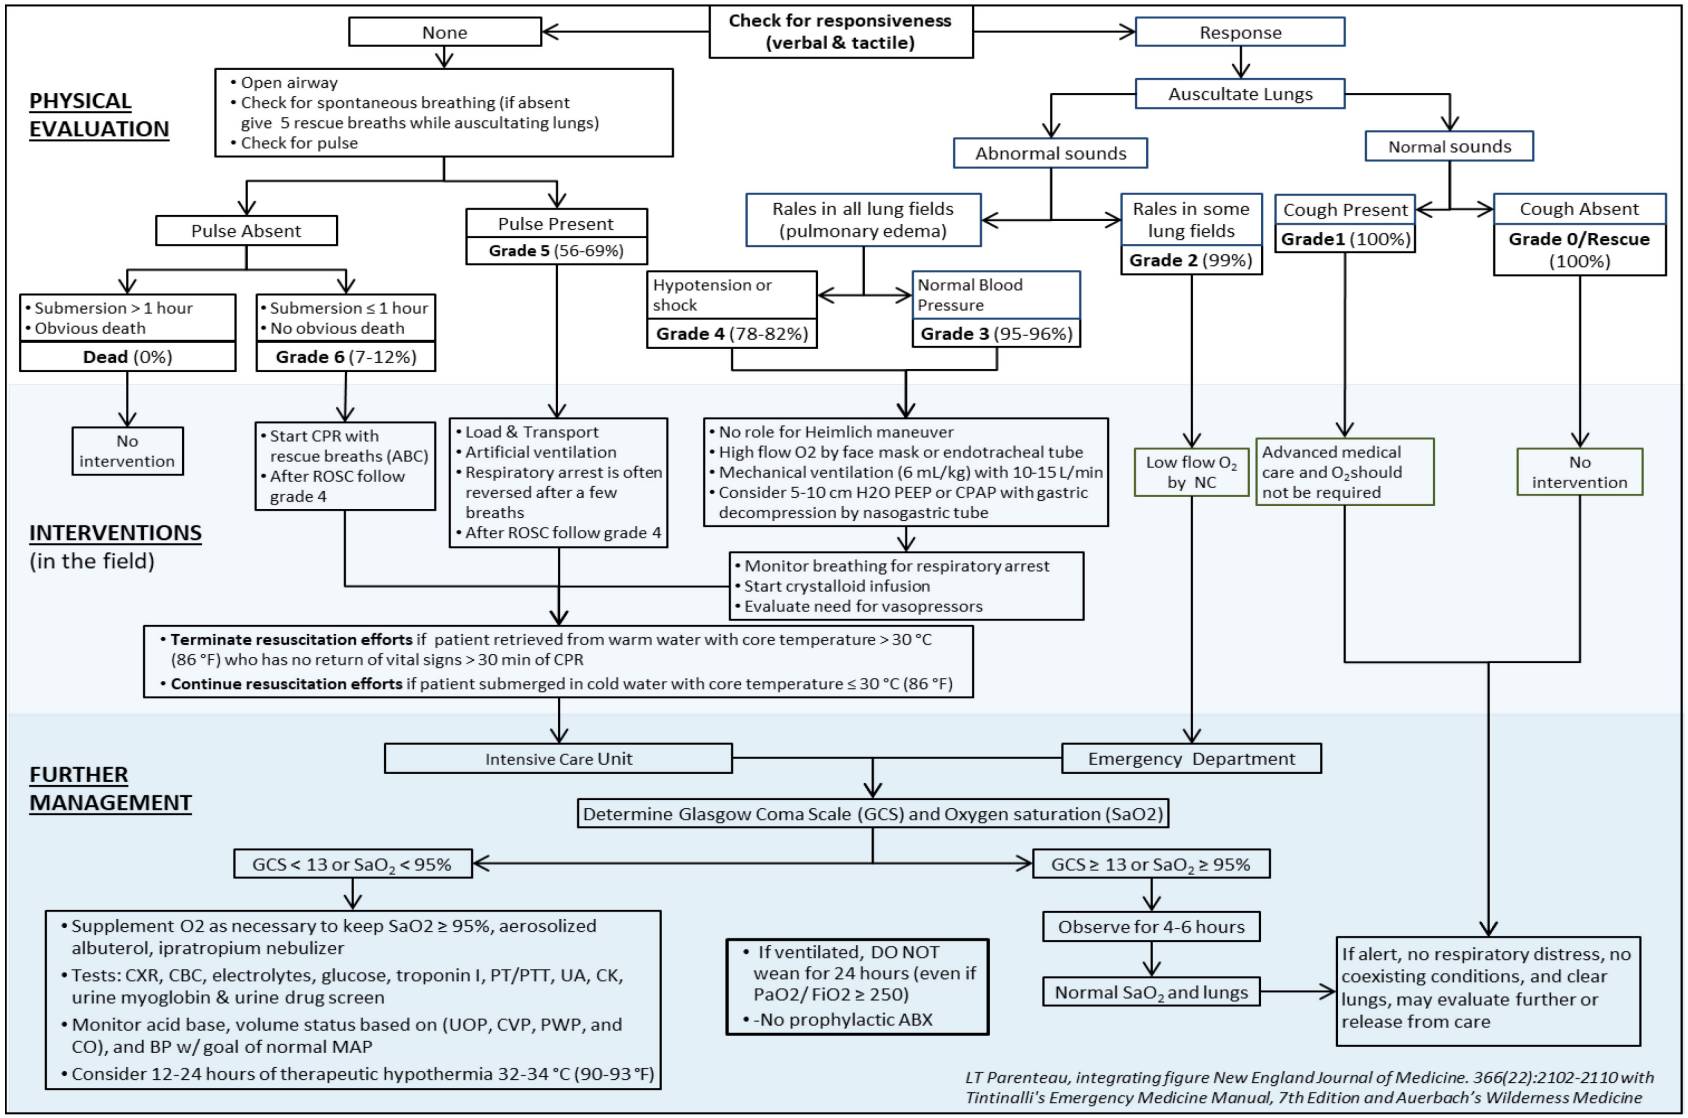
- Dyspnea or cough
- Hypoxemia
- +/- Hemoptysis
- CXR shows pulmonary edema or infiltrates that resolve w/in 48 hours.
- Absence of underlying pulmonary infection or aspiration of water

Pathophysiology: unknown; thought to be due to:

- Elevated pulmonary artery pressure - 'fracturing' pulmonary capillaries due to vascular stress caused by ↑ preload, afterload, and vascular resistance due to central pooling of blood from peripheral vasoconstriction.
- Diastolic dysfunction.

Management: typically resolves with rest within 24-48 hours. Hospitalization with diuretics and supplemental oxygen for severe cases.

DROWNING FLOWCHART



Check for responsiveness (verbal & tactile)
None
Response
PHYSICAL EVALUATION
• Open airway
• Check for spontaneous breathing (if absent give 5 rescue breaths while auscultating lungs)
• Check for pulse
Auscultate Lungs
Abnormal sounds
Normal sounds
Pulse Absent
Pulse Present
Grade 5 (56-69%)
Rales in all lung fields (pulmonary edema)
Rales in some lung fields
Grade 2 (99%)
Cough Present
Grade1 (100%)
Cough Absent
Grade 0/Rescue (100%)
• Submersion > 1 hour
• Obvious death
Dead (0%)
• Submersion ≤ 1 hour
• No obvious death
Grade 6 (7-12%)
Hypotension or shock
Grade 4 (78-82%)
Normal Blood Pressure
Grade 3 (95-96%)
No intervention
• Start CPR with rescue breaths (ABC)
• After ROSC follow grade 4
• Load & Transport
• Artificial ventilation
• Respiratory arrest is often reversed after a few breaths
• After ROSC follow grade 4
• No role for Heimlich maneuver
• High flow O2 by face mask or endotracheal tube
• Mechanical ventilation (6 mL/kg) with 10-15 L/min
• Consider 5-10 cm H2O PEEP or CPAP with gastric decompression by nasogastric tube
Low flow O_2 by NC
Advanced medical care and O_2 should not be required
No intervention
INTERVENTIONS (in the field)
• Monitor breathing for respiratory arrest
• Start crystalloid infusion
• Evaluate need for vasopressors
• Terminate resuscitation efforts if patient retrieved from warm water with core temperature > 30 °C (86 °F) who has no return of vital signs > 30 min of CPR
• Continue resuscitation efforts if patient submerged in cold water with core temperature ≤ 30 °C (86 °F)
FURTHER MANAGEMENT
Intensive Care Unit
Emergency Department
Determine Glasgow Coma Scale (GCS) and Oxygen saturation (SaO2)
GCS < 13 or SaO_2 < 95%
GCS ≥ 13 or SaO_2 ≥ 95%
• Supplement O2 as necessary to keep SaO2 ≥ 95%, aerosolized albuterol, ipratropium nebulizer
• Tests: CXR, CBC, electrolytes, glucose, troponin I, PT/PTT, UA, CK, urine myoglobin & urine drug screen
• Monitor acid base, volume status based on (UOP, CVP, PWP, and CO), and BP w/ goal of normal MAP
• Consider 12-24 hours of therapeutic hypothermia 32-34 °C (90-93 °F)
• If ventilated, DO NOT wean for 24 hours (even if PaO2/ FiO2 ≥ 250)
• -No prophylactic ABX
Observe for 4-6 hours
Normal SaO_2 and lungs
If alert, no respiratory distress, no coexisting conditions, and clear lungs, may evaluate further or release from care
LT Parenteau, integrating figure New England Journal of Medicine. 366(22):2102-2110 with Tintinalli's Emergency Medicine Manual, 7th Edition and Auerbach's Wilderness Medicine

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

Drowning casualties

INTENT (EXPECTED OUTCOMES)

Drowning casualties with cardiac arrest/CPR who have return of spontaneous circulation receive targeted temperature management therapy.

PERFORMANCE/ADHERENCE METRIC

Number and percentage of drowning casualties with cardiac arrest/CPR who have return of spontaneous circulation who receive targeted temperature management therapy.

DATA SOURCE

- Patient Record (paper medical record and electronic medical record)
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

- The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.
- The system review and data analysis will be performed by the JTS Chief and JTS PI Branch
- The Ustein Uniform Reporting Data form for Drowning will be used.

RESPONSIBILITIES

It is expected that medical department personnel, particularly of the sea services (U.S. Navy, U.S. Marine Corps, U.S. Coast Guard, and U.S. Merchant Marine) will become familiar with these clinical practice guidelines and incorporate them into both operational planning and emergency medical response plans.

APPENDIX A: MEDICAL DEFINITIONS AND TERMINOLOGY

WORLD HEALTH ORGANIZATION DEFINITIONS[1,2]

- **Immersion**: "some portion of the body is covered in water" (i.e. head is out of the water)
- **Submersion**: "during submersion, the entire body, including the airway, is under water" (i.e. head is in the water)
- **Submersion injuries**: "water-related conditions that do not involve the airway and respiratory systems
- **Drowning**: "the process of experiencing respiratory impairment from submersion/immersion in liquid." The drowning process begins with respiratory impairment as the person's airway goes below the surface of the liquid (submersion) or water splashes over the face while being completely in a liquid (immersion).[1-3] Subdivided into 3 categories:
  - **Fatal drowning**: "person dies at any time as a result of submersion/immersion with respiratory impairment."
  - **Non-fatal drowning with morbidity**: "person is injured at any time as a result of submersion/immersion with respiratory impairment, but survives."
  - **Non-fatal drowning without morbidity**: "person survives uninjured from submersion/immersion event with respiratory impairment, but survives."
- **Water rescue**: "submersion or immersion incident without evidence of respiratory impairment."[1-4]
- **Shallow water blackout**: "hyperventilating to decrease hypercapnic drive to breathe and prolong ability to stay under water such that hypoxemia results in unconsciousness." The compulsion to breathe from hypercapnia (acidosis) is physiologically more potent than hypoxemia (except when subverted by hyperventilation – i.e. lowering CO2).[5]
- **Asphyxia**: "a condition where breathing stops and both hypoxia and hypercapnia occur simultaneously due to: (1) the absence of gas to breathe; (2) the airway being completely obstructed; (3) respiratory muscles being paralyzed; or (4) respiratory center failing to send impulses to breathe." Running out of compressed air is a common cause of asphyxia in SCUBA diving.[1,5,6]
- **Drowning after shallow water diving**: Diving into shallow water makes concussion, head injury, and cervical spine (C-spine) injury more common, so rescuer must balance C-spine precautions against time of extraction (normally in drowning C-spine precautions are not required because the risk is < 0.5%). Also consider drug/alcohol impairment.[1,6]
- **Warm water drowning**: Unplanned submersion → panic and violent struggle → gulping / swallowing of air and water → breath holding until hypoxia leads to unconsciousness → gag reflex relaxing resulting in passive influx of water → drowning if PFD does not keep airway out of the water.[1]
- **Cold water drowning**: Impacts every organ system similar to complex trauma. Sudden immersion in cold water (< 91.4°F/33 °C) causes panic, reflexive gasp for air and rapid breathing making:[1-5, 8-10]
  - Inhalation/aspiration of water is more likely.
  - Core temperature drop causing arrhythmias, confusion, incapacitation (diminished strength and coordination) increasing the chance of drowning.

- Water conduct heat away from the body 25 times faster than air leading to immersion hypothermia – impaired meaningful movement usually precedes.[1,6,8]

TERMS NOT TO USE

Terms NOT to use as they do not have diagnostic or therapeutic distinctions (although still widely used by medical professionals and the lay public, so important to be familiar with them).[1,4,5,7,8,11]

- **Wet drowning**: "Fluid is aspirated into the lungs." Aspiration of water occurs in only 80-90% of cases and does not change the treatment or management.
- **Dry drowning**: "Fluid is not aspirated; death is due to laryngospasm and glottis closure." Asphyxia still occurs secondary to laryngospasm occurring in 10-20% of cases, but no change in management. Difference is only relevant at autopsy.
- **Secondary drowning/Delayed onset of respiratory distress**: Varied definitions with death occurring from 1-72 hours after initial resuscitation due to acute respiratory distress syndrome (ARDS). Fifteen percent of victims conscious at initial resuscitation subsequently die from ARDS.
- **Near drowning**: "Suffocation by submersion in a liquid with at least temporary survival. Death from near drowning occurs after 24 hours." Caused confusion because it had 20 different published definitions, most commonly if the person is rescued at any time, thus interrupting the process of drowning.
- **Immersion syndrome**: "Sudden death immediately following submersion in very cold water" thought to be caused by vagal nerve stimulation resulting in overwhelming bradycardia.
- **Active drowning**: Witnessed drowning
- **Passive drowning**: Unwitnessed drowning
- **Fresh water vs. salt water drowning**: Typical human aspiration during drowning is 4 mL/kg. To change blood volume requires 8mL/kg, or to alter electrolytes require 22 mL/kg. Therefore, not clinically significant and instead focus remains on hypoxemia, acidosis, and pulmonary injury rather than electrolyte or volume status.
  - **Freshwater**: Hypervolemia (in animal models only, not humans, so no clinical relevance)
  - **Saltwater**: Hypovolemia with hypernatremia (in animal models only, not humans, so no clinical relevance)

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Emergency General Surgery in Deployed Locations (CPG ID:71)

This CPG will guide providers in the evaluation and treatment of patients with acute general surgical needs in potentially austere locations

GOAL

The goal of this clinical practice guideline is to provide guidance on the treatment of acute surgical conditions in the deployed environment. These guidelines are not intended solely for clinical care, but to help unit commanders and supporting medical components to consider tactical and resource constraints relevant to the management of acute surgical conditions in order to optimize patient care in the expeditionary setting.

BACKGROUND

Austere surgical environments in a deployed setting can be significantly different from what medical personnel experience in garrison. The lack of diagnostic and treatment modalities can significantly limit management options. While deployed austere surgical capabilities are established for the primary purpose of trauma care and hemorrhage control, surgeons are still likely to deal with other urgent surgical issues.[1,2,3] The aim of this guideline is to provide surgeons in austere locations, as well as command staff, with decision support for the care of emergency general surgery patients.

EVALUATION

Depending on surgical team capabilities, a history and physical examination will be the mainstay of the diagnostic evaluation. In addition, the majority of surgical teams also have the capability for ultrasound and point of care blood analysis to allow for limited imaging and laboratory assessment. The most common non-traumatic surgical diagnoses to be encountered are shown in the table below:[1,2,3]

Table 1. List of Common Surgical Diagnoses

List of Common Surgical Diagnoses
Kidney stones
Appendicitis
Hernia
Testicular Torsion
Cholecystitis
Inflammatory bowel disease
Bowel obstruction
Ectopic pregnancy
Obstetric emergency
Ruptured ovarian cyst
Anorectal disorders (abscess, hemorrhoids, fissure)
Diverticulitis
Soft tissue infection/Abscess
Gastrointestinal bleeding

All the above diagnoses are familiar to general surgeons and history and physical examination alone will yield a high diagnostic accuracy.

In the non-deployed setting, the most important part of the evaluation is determination of the patient's clinical stability followed by timing of surgical intervention if warranted. In the resource-limited environment, many additional factors have to be considered in order to optimize the care of the patient with an acute surgical condition. Determining whether the patient is best served by having emergency surgery in an austere or resource-limited location or by transferring to a higher role of care is multifactorial.

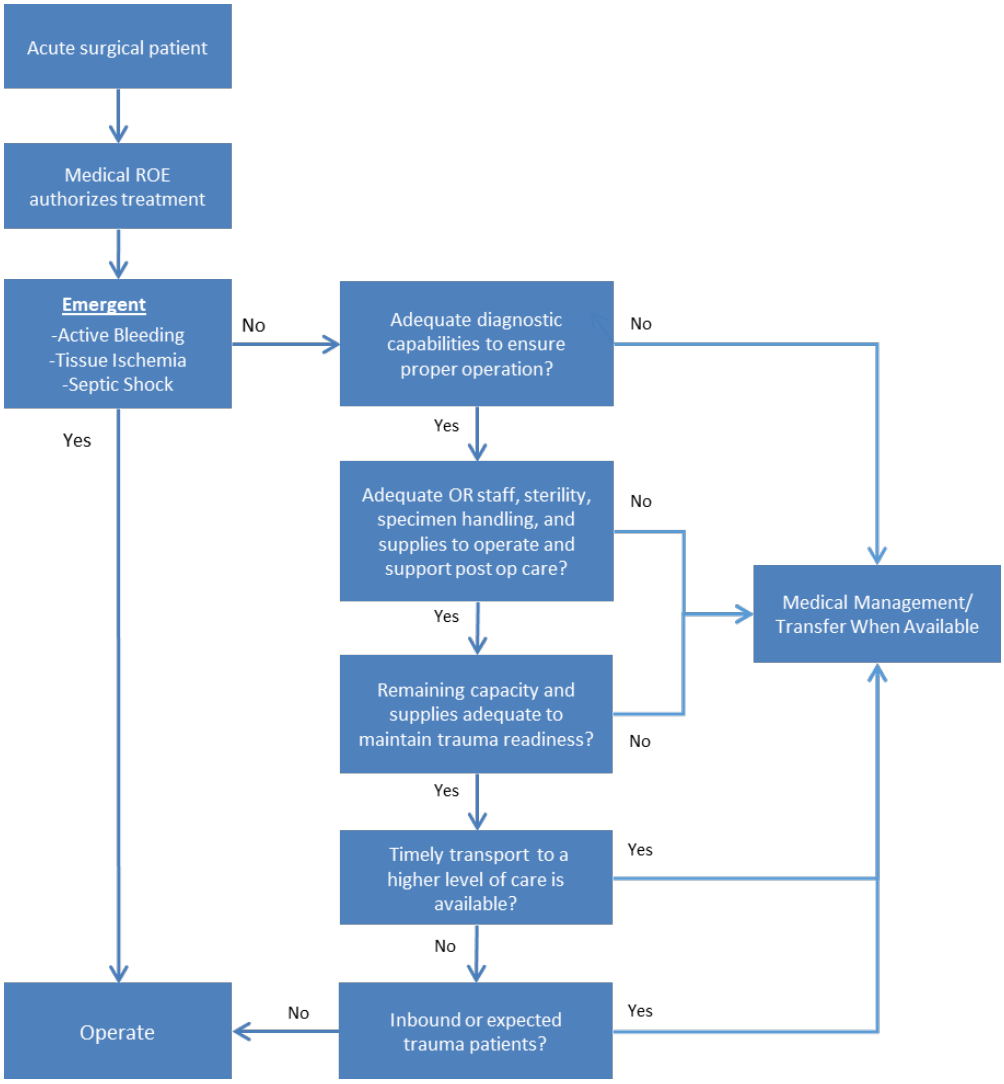
The deployed surgeon must consider complex tactical and clinical data in decision-making for clinically urgent situations. The surgeon must determine if the patient is emergent, requiring immediate intervention (e.g., ongoing bleeding, suspected tissue ischemia, or evidence of septic shock) or is nonemergent (localized findings, mild systemic symptoms). The clinical determination of stability is the most challenging for the deployed surgeon and their command staff alike. Except for gastrointestinal bleeding and tissue ischemia (e.g., testicular torsion, strangulated hernia), most patients with the previously mentioned surgical diagnoses will tolerate a delay of several hours with antimicrobial therapy before surgical intervention without increased morbidity or mortality. Therefore, these patients can be considered nonemergent.[4] While this delay in surgical treatment may not be ideal, it may be well within the standard of care. Some non-emergent invasive surgical procedures may be indicated in the austere environment depending on time to transport and complexity of the proposed intervention. For example, drainage of a soft tissue abscess may be indicated if transport to higher level of care will take multiple days.

DECISION MATRIX

Austere surgical environments and acute care surgery conditions are diverse and strict rules to cover every conceivable diagnosis would be inappropriate to a surgeon and commander. In all cases, the final clinical decision should rely on the surgeon at the forward location to act in the best interest of the patient. In real-world situations, the difference between emergent and nonemergent conditions can be clinically ambiguous when a host of additional factors are considered.

A graphical representation of considerations is presented above and discussed along with additional factors below.

Figure 1. Decision Matrix



1. Non-coalition patients: Patients may include local nationals, partner nation forces, contractors, foreign citizens, etc. Theater medical rules of eligibility (ROE) will dictate what care may be rendered, what transport resources will be available for use, and where these patients are to be transported for follow-on care. The principles of care should be equivalent to those provided to US/Coalition/enemy combatant patients, although operative decisions must be made in the context of the system of care in which that patient will be managed. Understanding of the medical ROEs and knowledge of the capabilities of the relevant systems of care are paramount.

2. Diagnostic capability: When conditions permit, the same preoperative, intraoperative, and postoperative standards of care should be provided to patients in a deployed location as in the United States. If a patient is non-emergent, reasonable attempts should be made to obtain appropriate diagnostic tests prior to surgical intervention, even if that requires transport to a higher role of care.

3. Operative team and supplies: Austere conditions are potentially not sterile and operative personnel may lack the subspecialty expertise for certain procedures or may be lacking the most appropriate supplies or

equipment needed. When conditions permit, procedures performed should be within the scope of practice of the deployed surgeon or should be done in close consultation with the appropriate subspecialist. In addition, specimens should be handled appropriately. Incidental neoplasms, while uncommon, do occur. Resected tissue should be evaluated by a pathologist and should be preserved appropriately for evaluation.

4. Holding capacity: If an operation is performed, the patient will have to be cared for postoperatively until transport or discharge is possible. If holding capacity is limited, a plan for transfer or discharge should be in place prior to the arrival of trauma patients.

5. Mission readiness: Non-emergent operations should not compromise the primary mission of the deployed team or the team's readiness to receive trauma patients.

6. Transport/receiving capability: If considering transport of the patient, the capability of transport vehicles and personnel may vary as well as the capabilities of receiving facilities. Knowledge of these capabilities and transport times are critical to making safe decisions. To the extent possible, communication with the transport team and the receiving provider should be made for patient safety and continuity of care.

7. Minor Procedures: If a procedure can be done in a clinic room, it can likely be done in an austere setting (i.e. thrombosed hemorrhoids, simple incision and drainage). Elective procedures should not be performed in the deployed setting. Elective minor procedures such as routine skin or soft tissue biopsies should not be done at a Role 3 unless in-house pathology is available as specimens can become lost or dry out while in transit for pathologic evaluation.

8. Teleconsultation: Whenever possible, particularly when surgical intervention for nonemergent conditions is being considered or when it is uncertain whether the condition is emergent or nonemergent, teleconsultation should be obtained with the surgeon at the next higher role of care if it is expected that the patient will require transfer postoperatively.

With the above listed considerations in mind, if the patient's clinical status is such that a delay in surgical treatment is likely to result in death or significant morbidity, they should be considered emergent and an operation performed. If not, strong consideration should be made to transfer the patient to a higher level of care unless, after considering the above points, in the surgeon's opinion the benefits outweigh the risks.

TREATMENT

The best interest of the patient is always the focus of decision-making for the surgeon; however, commanders are required to keep the tactical environment and risks aligned with the overall mission goals. In a setting of limited medical assets, determining the patient's clinical stability for transport as well as the availability of transport are extremely important factors to consider when determining the best treatment. The determination of emergent or nonemergent surgical status is therefore paramount and that decision may be appropriately influenced by availability and timing of transport to higher level of care. This distinction is based on the judgement of the surgeon on the ground, but emergent usually involves patients with tissue ischemia, ongoing bleeding, or evidence of septic shock. Emergent surgery should be done with treatment rendered based on damage control principles rather than in-garrison standards of care.[5] As in trauma, principles of surgical care should prioritize controlling sources of contamination and bleeding, with definitive care (e.g., anastomoses or ostomies) deferred for Role 3 or 4 facilities. In addition, heavily contaminated wounds should be left open for further washouts in a more sterile environment, if applicable.

Patients classified as nonemergent should be treated with the best available medical therapy and await transportation to a level of care that can definitively treat and hold patients for the perioperative period (See Decision Matrix; likely Role 3 or 4). This allows the austere surgeon to conserve supplies, equipment, and manpower for future emergent patients. Medical management may consist of broad spectrum antibiotics, resuscitation with fluids, pain control and supportive care as indicated. For some commonly encountered acute surgical diagnoses, medical management with ongoing close surgical observation may actually constitute definitive therapy.[6-10] The austere surgeon and the command element should have an awareness of the treatment options and how they fit into the multifactorial decision making. Treatment may entail medical management and observation within the forward surgical setting, transfer to higher level of care for definitive diagnosis, or disposition to quarters with a medical or non-medical attendant. Commanders and patients should be aware of these options with the associated risks. Clinical observation always carries the risk of deterioration requiring surgical intervention, therefore transfer to a higher level of care may be indicated even when non-operative management is selected.

While tailored antimicrobial therapy may be preferred for some diagnoses, this may not be possible given limited medication options in most austere packs as well as diagnostic uncertainty. Antibiotics should default to broad spectrum agents such as ertapenem given its widespread availability in austere surgical team packs, ease of administration and broad coverage. Given the low cross reactivity with penicillin-allergic patients, this common allergy should not dissuade surgical teams from administering ertapenam to patients with penicillin allergy.[11] Alternatives are disease specific, but consideration should be given to broad coverage from the onset of care. Lack of microbiology, culture and basic lab capability, combined with virulent local pathogens in many austere settings dictate this approach.

Unique to the military surgical environment is the need for maintain mission-readiness for the patient and their deployed unit. With mission requirements of foremost importance, the possibility of treating common surgical diseases, such as appendicitis and cholecystitis, non-operatively in an austere surgical setting should be considered and a high likelihood of success may be expected.[7,12] In-theater surgical treatment in austere locations with rapid return to duty may also be acceptable if resources and mission requirements permit. While patients are commonly instructed to limit physical activity for 6 weeks, there is little evidence-based support for this practice.[13] In cases of soft tissue abscesses and uncomplicated appendicitis, the expected post-operative morbidity would likely be low and the patient potentially safely and well-managed in the austere setting. However, for a nonemergent patient with suspected appendicitis seen in the Role 2 setting, strong consideration should be given to transferring the patient to a higher level of care in order to confirm the diagnosis with CT scan or if laparoscopic capability is available.

Nonemergent patients with acute cholecystitis should not be operatively managed at the Role 2 unless laparoscopic equipment, the appropriate operating room table and the ability to perform a cholangiogram (either flat plate or C-arm) is available as this is the standard of care and very rarely does a patient with acute cholecystitis require an emergent open cholecystectomy.

Although surgical site infections have been reported to be similar to civilian outcomes in one published experience, the surgical site infection rates are not negligible and other non-infectious perioperative complications may occur.[14] While transfer to a location that can deal with post-operative complications most effectively would be ideal, if the austere surgical team can safely and effectively perform the operation and manage perioperative complications an operation may be considered. Additionally, return to duty status should be taken into consideration along with long term post-operative morbidity such as hernia formation, the need for advanced pain management requirements (difficult in the austere or combat environment) and immediate post-operative complications.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients who undergo surgery for non-trauma diagnoses by deployed surgical teams.

INTENT (EXPECTED OUTCOMES)

- Patients receive initial treatment with antibiotics if infectious diagnosis (appendicitis, cholecystitis, abscess, diverticulitis).
- Emergency general surgery cases are performed at Role 3 or Role 4; if performed at Role 2, the indication to proceed with surgery rather than evacuate to higher level of care should be clearly documented.

PERFORMANCE/ADHERENCE METRICS

- Number and percentage of patients in the population of interest with an infectious diagnoses who receive antibiotics at the same role of care where diagnosed.
- Number and percentage of patients in the population of interest with emergency general surgery performed at Role 3 or Role 4; or if performed at Role 2, the indication to proceed with surgery rather than evacuate to higher level of care is clearly documented.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)
- Morbidity and Mortality Conference Reports

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Emergency Life-Saving Cranial Procedures by Non-Neurosurgeons in Deployed Setting (CPG ID:68)

This CPG applies to military non-neurosurgeons in a forward deployed location with surgical capability (Role 2 surgical teams that meet capability requirements) outside of the United States.

INTRODUCTION

The U.S. Military has deployed combat assets throughout the world. As such, catastrophic injuries can and do occur in austere environments with limited or no resources. It is understood that the standard of care for the treatment of severe traumatic brain injury includes the direct evaluation and treatment by a trained neurological surgeon.[1,2] Because there are not enough neurosurgical assets to support all missions, and because timely critical care air transport of severely brain injured servicemen and women is not always available depending on the location, and because severe and catastrophic brain injury can be rapidly fatal, the U.S. Military has recognized the occasional need for certain non-neurosurgeons (usually general surgeons) to perform cranial procedures far forward.[3] Data from the DoD Trauma Registry demonstrate that craniectomy procedures have been documented at Role 2 surgical facilities in Iraq and Afghanistan 36 times, with indeterminate success. There is some precedent for this practice within the literature,[2,5-6] including reference to the need for this practice as early as World War II.[7] This concept is addressed to a certain extent in the treatise on War Surgery from the International Committee of the Red Cross.[8] In the aforementioned references, there is tacit acknowledgement that neurosurgical procedures are possible in austere locations with appropriate training and resources. With this in mind, it has become the responsibility of the U.S. Military neurosurgical community to ensure that our deployed servicemen and women receive the best care possible from non-neurosurgical colleagues. The purpose of this clinical practice guideline is therefore to provide specific and tailored guidelines for the performance of cranial procedures by non-neurosurgeons. The document has been developed jointly by the neurosurgical departments of all three services to support the non-neurosurgeon faced with this difficult situation.

This CPG was developed by consensus opinion from the Joint Trauma System, neurosurgical members of the American Association of Neurological Surgeons/Congress of Neurological Surgeons (AANS/CNS), Joint Military Committee and the AANS/CNS Section of Neurotrauma. This document has been reviewed by and is supported by the Defense and Veterans Brain Injury Center.

Definitions
Craniotomy: The removal of part of the skull for the purposes of accessing contents of the calvarial vault, and then replacing the bone in its original position using plates and screws.
Craniectomy: The removal of portions of the skull for the purposes of accessing the contents of the calvarial vault without replacement of the bone.
Ventriculostomy: The placement of a small catheter within the body of the lateral ventricle through a small burr hole drilled approximately 10-11 cm posterior to the glabella and 2.5-3 cm lateral to midline. This catheter can be used to drain cerebrospinal fluid and to measure intracranial pressure.
Subdural hematoma: The accumulation of blood within the subdural space, usually as a result of trauma, and best diagnosed with a computerized tomography (CT) scan. Some general indications for surgery include hematomas > 1 cm in maximal thickness especially if associated with > 5 mm midline shift on a non-contrast CT of the head.
Epidural hematoma: The accumulation of blood within the epidural space, usually as a result of trauma, and best diagnosed with a CT scan. Common locations include the temporal region (middle cranial fossa) due to laceration of the middle meningeal artery. Some general indications for surgical intervention may include a hematoma > 30 mL in size on non-contrast CT head, especially if associated with evidence of uncal herniation. This can be clinically diagnosed when there is a dilated, unreactive pupil (3rd cranial nerve compression) with contralateral hemiparesis, with or without hemodynamic instability (hypertension, bradycardia, respiratory variation).
Intracerebral hemorrhage: The accumulation of blood within the parenchyma of the brain. This can result from trauma, and is best diagnosed with a CT scan.
Penetrating brain injury: Injury to the brain resulting from penetration of the skull, dura, and brain parenchyma by a foreign body.

INDICATIONS TO PERFORM CRANIAL PROCEDURES IN AUSTERE SETTING

The decision to perform a neurosurgical intervention in an austere location is best made with the telemedicine support of a neurosurgeon.

Telemedicine consult may be obtained from the closest neurosurgeon in the evacuation chain. In addition, worldwide neurosurgery consultation is available at:

- WRNMMC: 301-295-4000 (comm), 312-295-4000 (DSN) or 240-381-2528 (comm).
- SAMMC: 210-539-0817 (comm) or 312-429-2500 (DSN), 210-916-2500 (comm).
- Ask the hospital operator to contact the attending neurosurgeon on call.

In some locations, a CT scan may be available, greatly facilitating the appropriate intervention.

When a CT scan is not available, there is a high risk that procedures may be performed without correct localization of pathology. It is therefore necessary to make an accurate diagnosis, appropriately resuscitate, and exhaust all medical interventions prior to performing a procedure in this environment. Regardless of whether a CT scan is available, the indications for surgical intervention are clinical.

WHEN TO PERFORM CRANIAL PROCEDURES

- A cranial procedure is recommended after teleconsultation with neurosurgery (when possible), *and*
- Severe closed supratentorial brain injury with a presenting GCS ≤ 8 AND lateralizing cortical dysfunction such as unilateral dilated pupil or hemiparesis
  - Accompanied by hemodynamic dysfunction: hypertension, bradycardia, and respiratory variation (Cushing's reflex), *or*
  - Failure of maximal critical care management per the Neurosurgery and Severe Head Injury CPG2 to stabilize the patient. This may manifest by the occurrence of a new lateralizing cortical finding (hemiparesis, rapidly expanding pupil) and/or further decline in GCS off of sedation, *and*
- Evacuation to a neurosurgeon is not available within approximately 4 hours of injury, *and*
- Surgeon training and resources are adequate. See Appendix A (Training) and Appendix B (Resources).

WHEN NOT PERFORM CRANIAL PROCEDURES

- Clinical condition and neurologic status stabilized or improved with aggressive medical management.
- Surgeon and resources are not adequate. See Appendix A (Training) and Appendix B (Resources).
- The patient has a post-resuscitation GCS = 3 with bilateral fixed and dilated pupils. This is non-survivable.

CHECKLIST/PROCEDURES FOR CRANIECTOMY

1. Establish teleconsultation with neurosurgeon. Video consultation is preferred. If unable to communicate with a neurosurgeon, recommend a multi-disciplinary discussion that includes the local command authority prior to proceeding.

2. Make every effort to evacuate the patient to a facility where neurosurgery is available within approximately 4 hours.

3. Assess indications for craniectomy.
4. Assess availability of follow-on care.
5. Ensure that maximal medical/critical care management and resuscitation of the patient's intracranial condition has occurred. This should include appropriate blood component resuscitation, 3% saline, anticonvulsant, sedation, etc. in accordance with the JTS Neurosurgery and Severe Head Injury CPG.[2]
6. Ensure that the surgeon training and the facility resources are adequate.
7. If all of the above indications are met, then, in consultation with a neurosurgeon (when possible), consider intervention as follows: (Note: Review Emergency War Surgery Manual for further details.[3])

CLOSED HEAD INJURY

If no CT scan is available, an accurate neurological examination must be obtained for the purposes of localizing the lesion. A skull X-ray may improve localization in cases of skull fracture or penetrating brain injury.

Proper positioning of the patient is very important.

1. Avoid any compression of the neck to assure unhindered jugular venous outflow.
2. The head should be positioned slightly higher than the chest.
3. Rotate the head 30-40° off midline such that the side being operated on is highest.
4. Mark the midline of the scalp, as well as the location of anticipated burr hole and craniotomy incisions, prior to draping the head.

Once localized, exploratory burr holes will be made over the frontal, temporal and parietal convexities using electric drill for the purposes of identifying a hematoma.

1. If necessary, the dura can be opened carefully through the burr hole following cauterization if hemorrhage is subdural.
2. If evidence of epidural or subdural bleeding or high intracranial pressure is encountered, a craniectomy should be performed.
3. Burr holes alone are unlikely to be helpful in the setting of severe TBI.

Once the decision to proceed with craniectomy is made, the dura must be carefully separated from the inner table of the skull (Penfield 1-3 instruments) and the burr holes connected with the electric drill using either a side cutting bit or a "matchstick" bit.

1. An appropriately sized craniectomy is usually at least 15cm long in the sagittal plane and 12cm in height in the coronal plane, however a smaller craniectomy may be advisable in the far-forward setting.
2. Take care to stay off midline in order to avoid injury to the superior sagittal sinus.
3. If the hematoma is epidural, it must be evacuated and the bleeding source cauterized.
4. If subdural, the dura must be opened, the hematoma evacuated, and if visible, the bleeding source cauterized.
5. Do not replace the bone.
6. If not visible, do not search for a bleeding source.
7. If subdural hematoma, do not close the dura.

In all circumstances, the scalp must be closed.

If the brain herniates rapidly out after dural opening, close the scalp immediately.

PENETRATING HEAD INJURY

Penetrating brain injury is one of the most challenging indications for cranial procedures performed by neurosurgeons.

1. Exploration without teleconsultation from a neurosurgeon is not recommended.
2. There is often deep and uncontrollable bleeding that may not be evident on the cortical surface.
3. Surgical exploration below the surface of the brain is NOT recommended.
4. Surgical intervention should be limited to removing bone, opening the dura, controlling bleeding, and closing the skin rapidly.

If cranial contents are herniated from either the entry or exit wound, allow this to continue. Do not close the wound.

Adequately resuscitate as necessary, and transport at the soonest opportunity.

If evacuation to a higher level of care is not possible, recognize that intervention in this case may be futile.

PERFORMANCE IMPROVEMENT MONITORING

POPULATION OF INTEREST

All patients at a Role 2 surgical capability with an initial GCS ≤ 8 AND diagnosis of traumatic brain injury.

INTENT (EXPECTED OUTCOMES)

1. Cranial procedures will be performed by non-neurosurgeons only when a neurosurgeon is not available within approximately 4 hours.
2. Only patients with following criteria undergo decompressive craniectomy by a non-neurosurgeon:
    a. Traumatic brain injury with post-resuscitation GCS 4-8 AND
    b. Lateralizing neurologic signs AND
    c. Hemodynamic dysfunction (hypertension, bradycardia, and respiratory variation: i.e. Cushings reflex) OR failure of maximal critical care management (new lateralizing cortical finding such as hemiparesis or rapidly expanding pupil, and/or further decline in GCS off of sedation).
3. Non-neurosurgeons will perform emergency life-saving cranial procedures only after teleconsultation with a neurosurgeon.
4. Non-neurosurgeons will perform emergency life-saving cranial procedures using an electric drill and saw.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest with documentation of anticipated length of time > 4 hours to arrive at a facility with a neurosurgeon.

2. Number and percentage of patients in the population of interest who have the following indications documented:

   a. Traumatic brain injury with post-resuscitation GCS 4-8 AND

   b. Lateralizing neurologic signs AND

   c. Hemodynamic dysfunction (hypertension, bradycardia, and respiratory variation: i.e. Cushing's reflex) OR failure of maximal critical care management (new lateralizing cortical finding such as hemiparesis or rapidly expanding pupil, and/or further decline in GCS off of sedation).

3. Number and percentage of patients in the population of interest who have documentation of teleconsultation with a neurosurgeon.

4. Number and percentage of patients in the population of interest who have documentation of the use of an electric drill and saw for the procedure.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)
- ICU flow sheet

SYSTEM REPORTING & FREQUENCY

- The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.
- The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: TRAINING FOR CRANIAL PROCEDURES IN AUSTERE SETTING

The training and experience of individual surgeons is a factor that must be considered on a case-by-case basis when deciding whether to perform a neurosurgical intervention in an austere environment. In some cases a prolonged evacuation may be preferred over intervention by an untrained surgeon, while in other cases, such as with host national casualties, evacuation is not an option and the deployed care available is the only option.

Since neurosurgical training is not standard training for the majority of general surgeons, the following recommendations have been established to allow general surgeons to better prepare for austere surgical missions. The main purpose is to establish a guideline that, per expert opinion, optimizes the benefit: risk ratio for injured patients cared for in the forward deployed, resource limited environment.

Recommendations for non-neurosurgeons to perform cranial procedures for specific clinical indications in austere environments include:

- Board certified/eligible general or head and neck surgeon
- Participation in at least 10 cranial procedures supervised by a neurosurgeon. At least 1 of these procedures should occur within 1 year of scheduled deployment.
- Completed a cranial simulator course within 1 year of deployment run by a board certified/board eligible neurosurgeon (i.e. Emergency War Surgery Course or ASSET+).

Training recommendations do not constitute a credentialing requirement. Individual surgeons may perform cranial procedures when the clinical situation, available resources, and analysis of the risks and benefits of both surgical and medical management favor surgical intervention.

In cases where a surgeon has not completed the recommended training, the risk of neurosurgical intervention may outweigh the benefit and medical management may be preferred.

For context and perspective, the minimum number of trauma craniotomies required to graduate a neurosurgical resident trainee is 40. The committee of subject matter experts arrived at the number 10 in an effort to balance forward requirements with what was thought to be the necessary competency given the current training environment.

*Recommendations based on Consensus opinion American Association of Neurological Surgeons/Congress of Neurological Surgeons Joint Committee of Military Neurosurgeons, meeting 24 Apr 2017.

APPENDIX B: RESOURCES FOR CRANIAL PROCEDURES IN AUSTERE SETTING

Neurosurgical intervention is greatly facilitated by obtaining the recommended supplies and equipment. The risk of neurosurgical intervention is higher when proper equipment is not available. Every effort should be made to obtain the necessary supplies and equipment if neurosurgical procedures are within the scope of a surgical team's mission. If only a Gigli saw and Hudson brace are available to an inexperienced provider, the risk of neurosurgical intervention may outweigh the benefit, and medical management may be preferred.

Recommended resources necessary to support non-neurosurgeons who may have to perform cranial procedures in an austere environment should include all of the following:

1. Tele-conference capability (video-teleconference capability preferred).
2. Emergency cranial pack that includes an electric drill with cranial perforator bit and matchstick or cutting ball, a Leksell Rongeur, Penfield instruments, bipolar cautery, Dural substitutes, and hemostatic agents (i.e. gel foam, surgicel, etc.). A Gigli saw and Hudson drill may be included as back up should the electric drill fail during the procedure.
3. Critical care capabilities.

NOTE: Non-invasive measures of intracranial injury are an emerging technology that may be utilized to improve localization of injury or superficial hematoma.

Non-invasive Measurement Resources

1. Quantitative pupillometry: This is a small hand-held device that initiates a miotic pupillary response, records the speed of the response, and supplies a normative pupillary index (NPI).[1]
   - As intracranial pressure increases, the NPI decreases.
   - Asymmetric injury can result in asymmetric NPI and can aide with determining the hemisphere injured.
2. A handheld infrared scanner is another emerging technology for non-invasive brain imaging that may be considered to localize superficial intracranial hematomas.[2]

1. Taylor WR, Chen JW, Meltzer H, Gennarelli TA, et al. Quantitative Pupillometry, a new technology: normative data and preliminary observations in patients with acute head injury. Technical note. J Neurosurg. 2003:98(1);205-13.

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Emergent Resuscitative Thoracotomy (ERT) (CPG ID: 20)

Summarizes recommendations and technique for ERT in a Military Treatment Facility (MTF) in a combat or operational environment. The primary goal is to rapidly identify and correct any life threatening pathology and to provide care that results in a survivor with a meaningful level of function and cognition.

Appendix A: Recommended Algorithm for ERT in Traumatic Arrest 11
Appendix B: Technique of Emergency Resuscitative Thoracotomy 12
Appendix C: Additional Information Regarding Off-label Uses in CPGS 15

SUMMARY OF RECOMMENDATIONS & GUIDELINES *

Emergency Resuscitative Thoracotomy (ERT) is a potentially lifesaving intervention for patients who develop or have impending post-injury cardiovascular collapse or full arrest from a potentially reversible cause. While Resuscitative Endovascular Balloon Occlusion of the Aorta (REBOA) can be considered as an alternative in the absence of thoracic bleeding, there are still several indications for which ERT is a preferred or equivalent option.

The purposes of this procedure are:

- Control of intrathoracic hemorrhage
- Release of cardiac tamponade
- Internal cardiac massage
- Aortic occlusion to control infra-diaphragmatic hemorrhage and maximize cerebral and coronary perfusion.

Consider the following before performing ERT:

1. ERT should only be performed only at a forward military treatment facility with surgical and resuscitation capability (typically Role 2 or higher) and by individuals familiar with and trained in this procedure.
2. Absolute indications for ERT in the combat/operational environment include:
    - Penetrating truncal/extremity trauma with recent loss of vitals (less than 15 minutes) or impending cardiac arrest.
    - Blunt truncal/extremity trauma with pre-hospital vital signs and either witnessed arrest after arrival or refractory shock with impending cardiac arrest.
3. Additional relative indications for ERT in the combat/operational environment include:
    - Penetrating or blunt truncal/extremity trauma with pre-hospital arrest but with signs of life on arrival (narrow complex EKG rhythm and/or organized cardiac contractile activity on ultrasound)
    - Potentially salvageable blunt or penetrating cranial injury with vital signs and then arrest after arrival or impending arrest (uncommon)
4. ERT should NOT be performed for blunt trauma with arrest before arrival and with no signs of life (absent organized narrow complex EKG rhythm and/or organized contractile activity on cardiac ultrasound.)
5. ERT should NOT be performed during multiple or mass casualty (MASCAL) events or when performance will expend critical resources (such as blood products/surgeons/ORs) needed more salvageable patients.
6. The critical steps of an ERT include identification and release of tamponade, control of major thoracic hemorrhage, initiation of open cardiac massage, and cross-clamping the descending aorta.
7. The performance of a simultaneous right anterolateral thoracotomy or extension to a “clamshell” thoracotomy is indicated for evidence of right thoracic or mediastinal injury not reached from the left side.
8. Critical adjuncts to a successful ERT include adequate IV or IO access, endotracheal intubation, initiation of damage control resuscitation, and placement of an oro/naso-gastric tube.
9. For the patient with impending arrest, if immediate or direct transfer to the OR is available then this should be strongly considered versus performing an ERT in the resuscitation area.

10. All necessary equipment/supplies for ERT should be packaged together and stored in an easily accessible location in the resuscitation area, and should be regularly inspected and replaced/replenished as needed.

11. Trauma team training and simulation exercises should be performed at regular intervals and should include review of the necessary equipment, individual tasks, and sequence of events for an ERT

12. All personnel must wear full personal protective equipment and strict attention must be paid to control of needles/sharps to avoid iatrogenic injuries or infectious exposures (needle sticks, cuts, eye splash, etc.).

*These are general guidelines are not intended to replace expert clinical judgment and decisions based on evaluation of an individual patient, local capabilities, and operational considerations.

BACKGROUND

ERT, also called "emergency department thoracotomy," is an extreme procedure, performed in the small subset of patients who arrive either in full post-injury arrest, who rapidly progress to arrest after arrival, or who have impending arrest that precludes immediate transport to an operating room. Exsanguinated patients with profound hypotension or in hemorrhagic shock do not improve with external chest compressions.[1]

The physiologic rationale of ERT is based on both

1. treating several potential sources of bleeding (control cardiac or other intrathoracic bleeding and prevent infra-diaphragmatic exsanguination) and

2. restoring an adequate cardiac output (releasing pericardial tamponade, improving cerebral and coronary perfusion, performing open cardiac massage).

Resuscitative thoracotomy has been extensively described in the civilian trauma literature and has a high mortality rate, largely due to the nature of the injuries leading ERT.[2-5] The survival rates are highest (10 to 30%) for penetrating truncal injuries and patients who arrive with vital signs. They are significantly lower (less than 5%) for blunt trauma victims, particularly those who arrest in the field or during transport (1% or less). In addition, the likelihood of survival with intact neurologic function is significantly lower than the overall survival rates, particularly for blunt trauma victims and for pre-hospital arrest.

In a combat or operational environment, several specific factors must be considered as studies of wartime ERT are available and indicate that there is a reasonable probability of long-term survival and recovery following ERT in appropriately selected casualties.[6-10]

INDICATIONS FOR ERT IN CIVILIAN TRAUMA

In the setting of civilian trauma, ERT is generally indicated only for penetrating trauma with either witnessed cardiac arrest or recent loss of vital signs. These indications were formalized by a working group of the American College of Surgeons Committee on Trauma after collectively reviewing the results of over 4,500 ERT procedures.[3] There was an overall survival rate of only 5% for ERT, although survival was over 30% in patients with low velocity penetrating cardiac injury. When ERT was limited to penetrating trauma and appropriate indications, it is associated with an 8.8% survival rate. Although this remains a very low rate of success, ERT is a true salvage procedure, without which survival is essentially zero even in indicated scenarios. The working group formulated the following recommendations (Class II):

1. ERT is best applied to patients sustaining penetrating cardiac injuries that arrive at trauma centers after a short scene and transport time with witnessed or objectively measured signs of life (pupillary response, spontaneous ventilation, presence of carotid pulse, measurable or palpable blood pressure, extremity movement, or organized cardiac activity).

2. ERT should be performed in patients sustaining penetrating non-cardiac thoracic injuries, but these patients generally experience a low survival rate. Because it is difficult to ascertain whether the injuries are non-cardiac thoracic versus cardiac, ERT can be used to establish the diagnosis.

3. ERT can be performed in patients sustaining exsanguinating abdominal vascular injuries, but these patients generally experience a low survival rate. Judicious selection of patients should be exercised. REBOA may be an equally appropriate salvage procedure. This procedure should be used as an adjunct to definitive repair of the abdominal-vascular injury.

4. ERT should rarely be performed in patients sustaining cardiopulmonary arrest secondary to blunt trauma because of its very low survival rate and poor neurologic outcomes. It should be limited to those that arrive with vital signs at the trauma center and experience a witnessed cardiopulmonary arrest.

The Western Trauma Association (WTA) algorithm recommends ERT for patients with prehospital arrest and CPR duration of less than 10 minutes for blunt trauma and less than 15 minutes for penetrating injury.[5-11] ERT is also recommended for patients undergoing CPR with signs of life (respiratory or motor effort, organized cardiac activity, or pupillary reflexes) or with profound shock (systolic pressure < 60 mmHg). WTA's recommendation for ERT in blunt trauma patients with prehospital arrest and CPR<10 minutes is more liberal than others who recommend against ERT in this cohort; it is noteworthy, however, that this is based on only 5 patients (4 who arrived with organized electrical activity and 1 with tamponade from an atrial laceration).

Most recently, the Eastern Association for the Surgery of Trauma (EAST) Practical Management Guidelines for ERT analyzed 72 relevant studies utilizing the GRADE methodology for assessing the strength of the evidence, but also taking likely patient preferences into account.[12] They defined "signs of life (SOL)" as presence of any of the following: pupillary reactivity, spontaneous breathing, palpable carotid pulse, measurable blood pressure, motor movement, or organized electrical activity. They identified 6 pre-defined patient categories depending of 3 conditions (penetrating or blunt mechanism, thoracic or extra-thoracic location and presence of SOL), and made either strong or conditional recommendations for ERT in pulseless patients, as following:

1. Penetrating thoracic trauma with signs of life but pulseless on arrival (Strong).

2. Penetrating thoracic trauma without signs of life and pulseless on arrival (Conditional).

3. Penetrating extra-thoracic (non-cranial) trauma with signs of life but pulseless on arrival (Conditional).

4. Penetrating extra-thoracic (non-cranial) trauma without signs of life, pulseless on arrival (Conditional).

5. Blunt injury with signs of life but pulseless on arrival (Conditional).

6. For the sixth category of blunt trauma patients without signs of life and pulseless on arrival they gave a conditional recommendation against proceeding with ERT.

Results from prehospital thoracotomy has been reported by a few authors.[13,14] These studies concerned only the subgroup of stab wounds to the chest and described a 10 to 18% survival rate. This experience remains strictly limited to very few experienced teams acting within a trauma system with well-established training and quality assurance.

Recently, the prospective observational multicenter Aortic Occlusion for Resuscitation in Trauma and Acute Care Surgery study reported the outcomes of 310 patients undergoing ERT from 2013 to 2017 after either blunt or

penetrating trauma.[15] Survival rate was 12.3% beyond 24h and 5.2% to discharge. The authors discuss the fact that neither practice nor outcomes following ERT have changed in the last 40 years.

REBOA

Recently, the technique of REBOA has emerged in the setting of trauma for control of abdominal and pelvic hemorrhage. Although not strictly comparable, REBOA is a potential alternative to ERT to achieve aortic occlusion and, therefore, control of abdominal and pelvic hemorrhage. Several recent studies tried to compare REBOA and ERT in non-compressible torso hemorrhage[16-18,] and a meta-analysis is available.[19] Even if REBOA seemed to be associated with a lower mortality, there was no significant difference in survival after risk-adjustment, mostly because ERT patients were more critically ill on presentation. This suggests that REBOA is not a comparable intervention to ERT but rather may be utilized to prevent hemodynamic collapse in non-agonal unstable patients. Ongoing study is required to better illuminate the evolving role of REBOA as a potential replacement or as a preemptive adjunct to obviate ERT. Please refer to the JTS REBOA CPG for indications and details of this procedure.[20]

ERT FOR COMBAT CASUALTIES

SPECIFIC CONSIDERATIONS

In the battlefield or operational environment, several important additional factors must be considered. First and foremost is the major difference in the epidemiology of the injured patients presenting to military facility with surgical capabilities. Unlike civilian trauma victims, these patients will generally be younger and healthier and will largely have suffered penetrating or combined blast/penetrating type mechanisms.

Additionally, in combat or austere conditions, the local tactical environment and the impact thereof on critical resources may supersede clinical factors. ERT is a resource-intensive procedure that requires multiple personnel, specialized equipment, supplies, and potentially consumable resources (e.g., blood products- see below). Considering the low overall yield of ERT, the decision to proceed must be based not only on the individual patient factors, but also with consideration of the impact of the procedure on the MTF's overall capabilities. This issue is particularly critical at Role 2 facilities with significantly less personnel, equipment, and surge capacity compared to the more robust Role 3 and higher facilities. ERT should NOT be performed during MASCAL events or multiple casualty events where it would adversely impact the care of others with more survivable injuries.

Notably, careful attention must be paid to the impact of ERT on the local supply of blood products, with immediate early termination of aggressive blood product resuscitation if there is not a prompt response and return of circulation. Termination of efforts should also be considered in the patient with return of vital signs but ongoing major hemorrhage that will exhaust the local blood product supply and an overall low estimated probability of survival.

Pre-hospital thoracotomy on military patients is likely to require complex intervention in very challenging environments. Moreover, the evidence does not support the notion that earlier thoracotomy could improve survival.[21] ERT should only be performed in a setting and facility that has the capability and resources to provide the required level of care in the event of achieving return of circulation or stabilization of impending arrest. This generally limits this procedure to forward MTFs with surgical capabilities, proper equipment, and an adequate supply of blood products.

AVAILABLE LITERATURE

A study based on four-year data from a Role 3 facility in Iraq examined outcomes after ERT in the context of combat trauma.[8] ERT was successful in restoring a perfusing rhythm in half of patients, with 46% survival to the operating room. Although only 12% of patients survived through evacuation from the facility, all survivors were reported to have good functional outcomes. All survivors were reported to be neurologically intact, and there was no difference in survival based on injury mechanism, location or injury pattern. Explosive injury and gunshot wounds were the primary mechanisms of injury for patients in this series. This case series suggests similar or better survival after combat trauma ERT compared with civilian results of ERT. In a previous study limited to wartime penetrating thoracic trauma with cardiac injuries, among 17 patients undergoing ERT, a 24% survival rate was reported.[22]

These results were confirmed in a more recent study examining outcomes among 65 patients who underwent ERT at a single Role 3 facility in Afghanistan.[9] The mechanisms were again all blast and gunshot wounds, and the overall survival rate was 22%. Although there were no survivors among patients with traumatic arrest in the field, there was a 10% 30-day survival among patients who had vital signs in the field and subsequently arrested during transport and 42% for those who arrested after arrival at the MTF. This study also demonstrates the critical aspect of time from arrest to ERT, with survivors having an average time of 6 minutes versus 18 minutes for non-survivors.

A recent retrospective 8-year study of Operations Enduring and Iraqi Freedom resuscitative thoracotomies showed a 9.9% survival rate among 81 patients.[10] Survivors had significantly higher extremity Abbreviated Injury Scale, (suggesting the usefulness of aortic occlusion in penetrating pelvic or junctional exsanguination), higher initial oxygen saturation, and higher post-procedural blood product and volume resuscitation (possible survival bias). Although not statistically significant, all survivors also had an explosive/blast mechanism. This work suggests that ERT may improve the outcomes in primary extremity blast injuries who were in extremis at arrival.

RECOMMENDATIONS

A recommended algorithm for ERT in traumatic arrest in the combat or operational environment is presented in Appendix A.

PENETRATING INJURIES

- Resuscitative thoracotomy at an MTF in the combat or operational environment is most strongly indicated and warranted in patients with penetrating injuries who present to an MTF in extremis or with a recent witnessed loss of vital signs, especially those with penetrating thoracic injuries. Although there is controversy on the exact definition of “recent” loss of vital signs, the majority of data supports up to 10-15 minutes as a cutoff for pre-hospital arrest with penetrating truncal or extremity trauma.
- Though most of these casualties will not survive, up to 25% of penetrating trauma patients who undergo ERT at a forward military facility can be salvaged with acceptable neurological outcomes.

BLUNT TRAUMA

- In the deployed setting, victims of blunt trauma are less common but most commonly present after vehicle crashes or falls from height. The previously noted study from a combat trauma setting found no ERT survivors after blunt injury, although the blunt cohort was small.
- In the operational setting, ERT for blunt trauma should be based upon clinical judgment, recognizing that the data from civilian studies has demonstrated a very low survival rate. It should be limited to those who have either witnessed in-hospital arrest, pending arrest, or those with definite vital signs in

the field and who arrive with clear and present signs of life (organized narrow complex EKG and/or organized cardiac contractile activity on bedside cardiac ultrasound).

- Blunt trauma patients with no vital signs at the scene of injury and during transport, or with reported vital signs during transport but who arrive in arrest should NOT have ERT performed.

SPECIAL CIRCUMSTANCES

- Patients with injuries that have a low likelihood of salvage, such as traumatic brain injury or high total body surface area burns, should be either declared expectant on arrival or at most managed with non-operative resuscitation and interventions (intubation, chest tubes, fluid/blood resuscitation) and then reassessed.
- In patients with arrest or impending arrest with severe blunt or penetrating traumatic brain injury, ERT is generally contraindicated unless there is evidence of preserved neurologic function and a potentially salvageable and survivable brain injury.

REBOA to control life-threatening sub-diaphragmatic hemorrhage in surgically capable theater facilities may be a selective alternative to ERT, as detailed in the JTS REBOA CPG.[20]

TECHNIQUE

The objectives of the ERT are always the same, no matter the injuries: to stop the bleeding and restore adequate central perfusion. Immediate attention should be paid to the most lethal potential findings, such as cardiac tamponade, penetrating cardiac injury, great vessel injury, and massive pulmonary injury. In the event that the injury is on the right side of the heart or chest, the standard ERT incision may be extended to the bilateral thoracotomy or "clamshell" incision with extension across the sternum. ERT is a well-codified procedure that can be considered in several steps:

1. Left anterior-lateral thoracotomy incision
2. Opening the pericardium
3. Control of a cardiac injury
4. Temporary control of active lung bleeding
5. Cross-clamping of the descending aorta
6. Internal cardiac massage and defibrillation
7. Repair of other thoracic, abdominal or peripheral injuries

Concurrent massive transfusion protocol, as well as potential pharmacological adjuncts, is essential. Rapid successful restoration of cardiac function is the key to deciding on the relevance of continuing the procedure.

The detailed technical steps are presented in detail in Appendix B.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

Patients with AIS chest, abdomen, pelvis, and/or lower limb ≥3 with SBP >0 and <90 or CPR in progress on arrival to first MTF AND not isolated head injury (AIS head/face/neck = 5 or 6).

INTENT (EXPECTED OUTCOMES)

ERT is not performed in patients with no signs of life or CPR >15 minutes or isolated severe TBI.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients who underwent ERT (or REBOA) in the population of interest.
2. Number and percentage of patients who did not undergo ERT (or REBOA) in the population of interest.
3. Number and percentage of patients who underwent ERT who survived 24 hrs, 7 days, 30 days (assume alive if discharged alive prior to each time point).
4. Number and percentage of patients who did not undergo ERT (or REBOA) in the population of interest who were declared KIA/DOA or who survived 24 hrs, 7 days, 30 days (assume alive if discharged alive prior to each time point).

DATA SOURCES

- Patient Record.
- Department of Defense Trauma Registry (DoDTR)
- Morbidity and Mortality Conference Reports

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

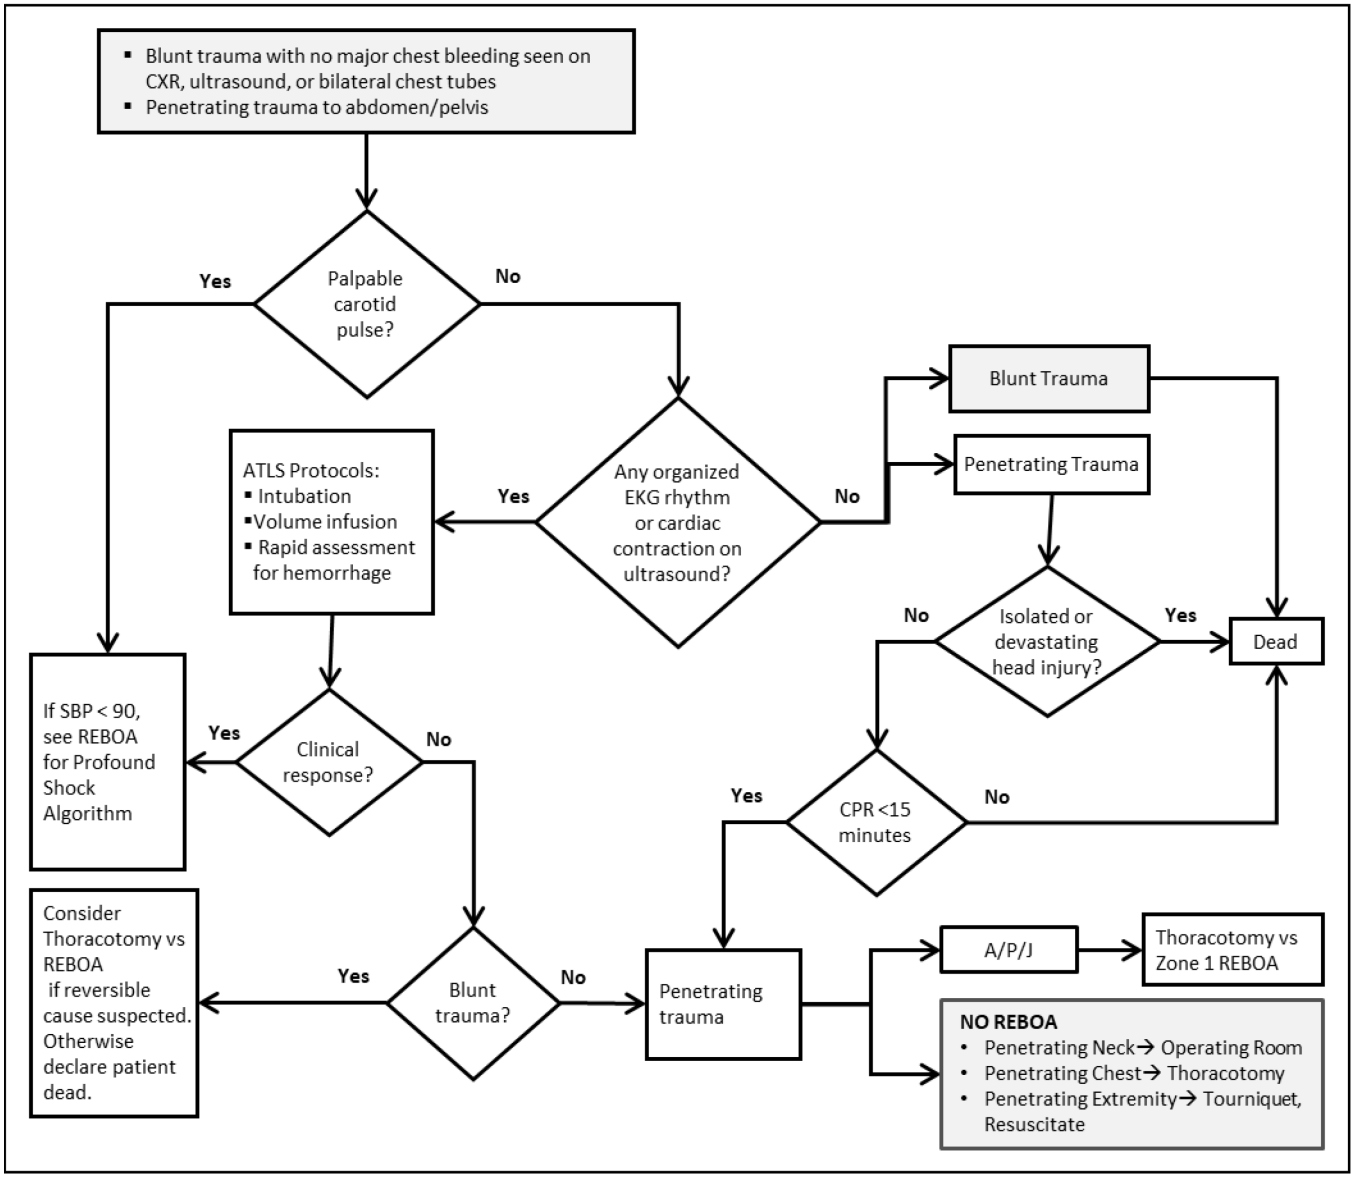
APPENDIX A: RECOMMENDED ALGORITHM FOR ERT IN TRAUMATIC ARREST



APPENDIX B: TECHNIQUE OF EMERGENCY RESUSCITATIVE THORACOTOMY

PREPARATION

All emergency and surgical personnel at a Role 2 or higher facility should be trained in their roles and actions to facilitate performance of an ERT.

All needed supplies and equipment for an ERT should be pre-packaged and stored in a readily accessible location in the resuscitation area, and periodically inspected for completeness and service ability.[23]

The surgeon and designated team members should review the contents and composition of the ERT supply package.

All personnel performing, assisting, or otherwise participating in an ERT should be wearing full personal protective equipment including a gown, gloves, and eye protection.

The urgency of the procedure, coupled with the mix of multiple assistants and multiple potential sharps represent a high-risk scenario for accidental injuries and infectious disease exposure to the involved medical personnel (See JTS Infection Prevention in Combat-Related Injuries CPG.[24] Great care must be taken during training and actual ERT procedures to highlight safety precautions including control of all needles, syringes, scalpels, and other sharps.

Sterile preparation is not required for ERT, as the nature of this procedure does not afford the time for prep solutions to dry and assume their antimicrobial efficacy.

If at all possible, definitive airway control should be obtained prior to or during ERT, but ERT should not be delayed solely to establish a secure airway.

Efforts to obtain adequate intravenous or intraosseous access for blood product infusion should proceed simultaneous to ERT, keeping in mind that in the case of penetrating thoracic trauma, infusions via the upper extremities may be ineffective until bleeding is controlled. Similarly, lower extremity, pelvic, or abdominal wounds with exsanguination should be resuscitated via an upper extremity or central venous catheter. In the patient with difficult intravenous access, intraosseous access should be immediately established, preferably in the sternum or humerus.

Placement of a right chest tube if there is any possibility of injury/hemorrhage on the right side should be strongly considered. Alternatively, the right chest may be open through an extended thoracotomy or clamshell incision.

Effective suction should be available for successful ERT.

INCISION AND EXPOSITION

1. ERT begins with a generous curvilinear left anterolateral thoracotomy (from the sternum to the table) at approximately the fourth intercostal space. If previously performed, a tube thoracostomy incision can serve as a starting point for the thoracotomy. Exposure can be significantly improved by placing a towel or roll under the left back to elevate and rotate the left chest.

2. The nipple line in males and the inframammary crease in females is a reasonable anatomic landmark (time should not be spent attempting to count ribs). If in doubt, it is best to err more superiorly rather than make too low an incision.

3. After the initial incision with a knife to/through the level of the chest wall muscles, heavy scissors may be used to rapidly and safely open the remaining tissues through the full extent of the incision by sliding the partially opened scissors along the superior rib border.

4. The internal mammary vascular pedicle is located 1-2cm lateral to the sternal border and will be transected during ERT. Transection of these vessels is of no physiologic consequence, but control of associated bleeding (only after return of circulation in case of successful procedure) with suture or clips will be necessary.

5. If after initial left ERT, additional right-sided thoracic, cardiac or pulmonary hilar exposure is needed, the incision should rapidly be extended across the sternum (with a Lebsche knife or simple trauma shears) and continued on the right side (bilateral thoraco-sternotomy or "clamshell" incision).

6. Once the incision is completed, a rib retractor is placed (with the handle downward), the ribs are spread and the lung is initially packed posteriorly with laparotomy pads or sterile towels, or manually retracted by an assistant; this can be facilitated by incision of the inferior pulmonary ligament. After evacuating blood and/or formed clot from the left pleural space, the pericardium is visualized to assess for cardiac activity and for hemopericardium.

   NOTE: One of the most common technical errors in ERT is poor exposure due to inadequate length of the skin incision and lack of complete division of the subcutaneous and muscle layers.

CARDIAC PROCEDURES

1. Pericardotomy: The pericardium is opened longitudinally at least one finger breadth anterior to the phrenic nerve which can be identified in its cranio-caudal course along the lateral pericardium, generally within 1-2cm of the pulmonary hilum. The pericardium should be opened by grasping with a forceps and using a tissue scissor, followed by extension down to the diaphragm and cephalad to below the thoracic inlet. In cases with a large hemopericardium, tension may make grasping the pericardium with forceps difficult. The heart can then be delivered partially out of the pericardium to inspect for injury and facilitate open cardiac massage if needed.

2. If after pericardiotomy, a cardiac injury is identified, initial temporary control may be achievable with digital pressure, a large side-biting clamp, a Foley catheter, or even a surgical skin stapler.

3. In the absence of effective cardiac activity, open cardiac massage should be rapidly instituted at this point using a two-handed technique, which is less traumatic and produces a better cardiac output. This will be ineffective unless concurrent volume resuscitation has occurred sufficient to provide adequate preload.

4. Defibrillation must be early attempted in cardiac arrest. If internal paddles are available, an electric shock is typically delivered at 20 Joules. If not, external paddles can also be used in the usual cutaneous position at 200 J, after temporarily removing the costal retractor so as to briefly close the chest cavity.

5. If there is no cardiac injury and no cardiac activity (asystole), resuscitative efforts should be terminated after a reasonable time (5-10 minutes).

6. In case of successful restoration of cardiac activity, cardiac or other intrathoracic injuries should be more definitively repaired, and exploration completed.

AORTIC CROSS-CLAMPING

1. If there is known or suspected hemorrhage from below the diaphragm, initial attention after thoracotomy should be focused on clamping the descending thoracic aorta. The lung is retracted and packed anteriorly and superiorly to identify the aorta in its location just anterior to the vertebrae. This can be facilitated by incising the inferior pulmonary ligament.

2. The aorta should be clamped just above the diaphragm to maximize collateral flow and spinal cord perfusion. In exsanguinated or asystolic patients (i.e. with a "flat" aorta"), the esophagus is easily mistaken for the aorta. Placing an orogastric or nasogastric tube will help identify and avoid injury to the adjacent esophagus (located just medial/anterior to the aorta).

3. Opening the mediastinal pleura, limited blunt dissection is used on either side of the aorta to facilitate the placement of a large, atraumatic DeBakey vascular clamp.

4. After the clamp is placed, aggressive resuscitation may be instituted and immediate plans made for direct surgical control of the patient's injuries. If a patient remains severely hypotensive despite fluid resuscitation after aortic clamping, it is unlikely that he has a survivable injury.

5. The duration of intra-thoracic aortic cross clamp should be carefully monitored, and the maximum tolerated duration in the patient already in hemorrhagic shock is 30-40 minutes. It should be removed at the earliest possible time, or the level of cross clamp could be moved inferiorly to the abdominal aorta or iliac vessels if proximal control of abdominal, pelvic, or extremity vascular injuries is still required. Once the injury is addressed, as the clamp is removed, the team should be prepared for rapid hemodynamic shifts and the potential development of hyperkalemia and/or metabolic acidosis (ischaemia-reperfusion injury or "reperfusion syndrome.").

INJURY WITHIN THE THORAX

If after thoracotomy, there is a direct injury to the lung or hilar vessels, direct pressure (with a finger, rolled gauze, or laparotomy sponge) is generally sufficient for temporary control of bleeding in this low pressure system. Using lap pads to collapse the lung parenchyma medially will pack the hilum and free up your hands initially to allow a more detail inspection of the chest, heart, and vessels for sites of hemorrhage, and allow the placement of the aortic clamp. Some major pulmonary injuries might need early hilar cross-clamping en masse.

Once temporary control is in place, resuscitation can be instituted and the patient may be taken to the operating theatre for definitive lung repair with stapled resection, suture repair, stapled "tractotomy," or in extreme cases pneumonectomy (which carries a very high mortality in the trauma setting, even in the absence of pre-procedural arrest).

Large pulmonary injuries also create a risk for air embolism which can result in entrained air entering the pulmonary veins and subsequently the left heart and coronary vessels. Early pulmonary hilar clamping, rapid direct control of lung lacerations or temporarily submerging the area in irrigation fluid can help prevent this risk.

If there is a thoracic great vessel injury, temporary control may be achievable with digital pressure or atraumatic vascular clamps. If these are insufficient to control a great vessel injury in the setting of an ERT, this likely represents a non-survivable injury.

Unlike pulmonary bleeding, intercostal and chest wall bleeding is under arterial pressure and will require more focal and firm pressure for initial control, followed by mass suture ligatures and/or clip

APPENDIX C: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Eye Trauma: Initial Care (CPG ID:03)

This CPG provides a step-by-step approach for the non-ophthalmologist in the initial evaluation and treatment of eye trauma injuries sustained in the combat theater or in remote and austere environments.

SUMMARY OF CHANGES

- Antibiotics for open globe and intraocular foreign body (IOFB)
- Aeromedical evacuation considerations
- Lateral canthotomy, inferior cantholysis technique with instructional pictures

BACKGROUND / EXECUTIVE SUMMARY

- Eye injuries are common in warfare.[1-3] During Operation Enduring Freedom (OEF) and Operation Iraqi Freedom (OIF) 10-15% of combat-related trauma injuries involved the eye. [4]
- Significant numbers of potentially serious eye conditions can arise in non-battle environments and during non-battle activities.[1]
- A large percentage of serious and/or blinding eye injuries can be prevented by wearing approved combat eye protection[4] from the Authorized Protective Eyewear List (APEL) available at https://www.peosoldier.army.mil/equipment/eyewear/.
- The eye is extremely intolerant of injury.
  - Eye trauma requires prompt evaluation and treatment by an eye surgeon.
  - The foundation for successful treatment and preservation of vision is most often laid in the **initial phases** by forward medical providers at all echelons of care.
- Ophthalmic resources are deployed increasingly sparingly in very select locations.
  1. Initiate teleophthalmology consultation with eye surgeon as soon as possible. (See Teleophthalmology.)
  2. Evacuate all vision-threatening injuries so that they receive treatment by an eye surgeon within 24 hours, if possible.
     - Factors such as combat operations, aircraft availability, weather, proximity to port, transport safety and security can affect the timing of transfer and definitive treatment.
     - When evacuation to an eye surgeon is delayed or caring for ocular injuries in the Prolonged Field Care Environment, see the *Joint Trauma System Ocular Injuries and Vision-Threatening Conditions in Prolonged Field Care Clinical Practice Guideline, 01 Dec 2017*.

GOALS OF EYE TRAUMA CARE

PRIORITIES

Maintain high index of suspicion based upon the mechanism of injury.

Eye Exam

- When possible, assess and document, at a minimum, visual acuity.
- Examine for critical findings. (See below.)

Management

1. Recognize and immediately treat the two traumatic eye emergencies listed below:
   a. For chemical injury, ***irrigate immediately and copiously***. (See Chemical Injury.)
   b. For orbital compartment syndrome, perform immediate lateral canthotomy and inferior cantholysis. (See Orbital Compartment Syndrome.)
2. **SHIELD AND SHIP** vision-threatening eye injuries:
   a. Protect injured eyes (known or potential injuries) with a rigid eye shield immediately (i.e. "Eyepro" or "Fox shield").
   b. Maintain patient comfort, treat pain and nausea.
   c. Prevent further damage.
   d. Do **NOT** put pressure on eye with suspected open globe injury.
   e. Initiate teleophthalmology consultation with eye surgeon as soon as possible. (See Teleophthalmology.)
      - Urgent: Call Role 3 or Role 4 with an eye surgeon (ophthalmologist).
      - Non-urgent: Contact Role 3 or Role 4 with an eye surgeon (ophthalmologist). Can use Pacific Asynchronous TeleHealth (PATH)/ Health Experts online Portal (HELP) web-based system if no ophthalmologist in theatre.
   f. Evacuate all vision-threatening injuries so that they are able to receive treatment by an eye surgeon within 24 hours when possible.

Prevent Eye Injuries

1. Encourage wearing only approved eye protection in accordance with unit guidelines and requirements. Examples: Military Combat Eye Protection (MCEP), Ballistic Protective Eyewear (BPE), "eyepro," or "eye armor." (See Protective Eyewear.)
2. Discourage contact lens use.

EYE HISTORY

"Keep an eye out" for eye trauma.

1. Maintain high index of suspicion based upon mechanism of injury.
   - Blast injury - most common cause eye injury in OIF and OEF.[5,6]
   - Direct facial and eye trauma.
   - Cranial or brain injury.[5,7]

- Metal on metal mechanisms (metallic fragments can penetrate without obvious signs on exam).
- Compressive blunt force trauma (can cause ruptured globe).
- Multisystem trauma. It is easy to overlook ocular trauma.
- Unconscious patient who cannot report vision change.
- Thermal burns, especially to the face.

2. If patient can follow commands, ask about eye symptoms such as vision loss, decreased vision, double vision, or eye pain.
3. Ask if casualty was wearing MCEP, BPE, "Eyepro," or "eye armor" at time of injury. Review past eye history, including use of glasses or contact lens.
4. Review tetanus status.

INITIAL EYE EXAM[8]

VISION

1. Assess and document visual acuity for each eye if possible. (See Visual Acuity Testing.)[8]
2. Presenting vision may be the best predictor of final visual outcome.[9]

INTRAOCULAR PRESSURE (IOP)

1. Do NOT put pressure on eye with suspected open globe injury.
2. If orbital compartment syndrome is suspected, palpate eyelids to see if one eye has increased firmness and resistance compared with the opposite eye ("rock hard" eyelids).
3. Do not attempt to check IOP at Role 1 or 2 unless experienced with this technique.

PUPILS

Test for relative afferent pupillary defect (RAPD) using swinging flashlight test. (See RAPD Testing.)

EXTRAOCULAR MOTILITY

If patient can follow commands, ask to follow your finger without moving the head. Record any restrictions to movement.

EXAMINATION

Examine for critical findings. Perform focused eye exam "outside to inside."

- External Exam – face, bony orbit, eyelids.
- Eye – conjunctiva, cornea, anterior chamber, iris, lens. (See Eye Anatomy.)
- Unless experienced, do not attempt fundus/posterior segment examination at Role 1 or 2.

- Do NOT attempt ultrasound of the injured eye because it places pressure on the eye.

SHIELD AND SHIP

SHIELD AND SHIP vision-threatening eye injuries [10-11]

1. Protect injured eyes (known or potential) with a rigid eye shield immediately - Eyepro or Fox shield. (See How to Place Eye Shield.)
   a. Base protection choice upon findings of eye history and exam.
   b. Treat eyelid injuries like an open globe.
2. Maintain patient comfort during transport.
   a. Prevent Valsalva which can increase the risk of extrusion of intraocular contents.
   b. Provide pain control and sedation as needed.
   c. Treat nausea and vomiting aggressively (Ondansetron 4-8 mg IV).
   d. Avoid strenuous movements.
   e. Bed rest with head elevated 30 degrees if possible.
3. Prevent further damage. **Do no harm.** (See Do No Harm Section below.)
   Do NOT put pressure on eye with suspected open globe injury.
4. Initiate teleophthalmology consultation with eye surgeon as soon as possible.
   (See Teleophthalmology.) Provide focal history, exam, and photographs when able.
5. Evacuate all vision-threatening injuries so that they are able to receive treatment by an eye surgeon within 24 hours if possible.
   a. Teleophthalmology consultation with an ophthalmologist is recommended before fixed wing transport (see Aeromedical Transport Considerations).
   b. When in doubt: SHIELD AND SHIP.

DO NO HARM (DO NOT'S)

1. DO NOT let a suspected eye injury leave your level of care without rigid eye protection.
2. DO NOT patch. It puts pressure on eye. **(*DO shield but DO NOT patch.)***
3. Do NOT wrap. It puts pressure on eye.
4. Do NOT place anything under an eye shield, including gauze.
5. DO NOT put pressure on eye with suspected open globe injury; it may increase the risk of extrusion of intraocular contents.
6. DO NOT check intraocular pressure at a Role 1 or 2. (Eye surgeon will check at Role 3 or 4.)
7. Do NOT attempt ultrasound of the eye. It places pressure on the eye.
8. DO NOT remove impaled or resistant foreign bodies.
9. DO NOT attempt to repair eye.

10. DO NOT enucleate or debride tissue, even if eye is severely traumatized.

TELEOPHTHALMOLOGY [12]

1. Management of eye injuries is complex. Recommendation is to engage an eye surgeon via teleophthalmology consultation as soon as possible.
2. Teleophthalmology improves and extends ophthalmic care to remote deployed locations.
   - **Urgent:** Use phone or video teleconference service to call a Role 3 or Role 4 with an eye surgeon (ophthalmologist).
   - **Non-urgent:** Contact Role 3 or Role 4 with an eye surgeon (ophthalmologist). Can use Pacific Asynchronous TeleHealth (PATH)/Health Experts online Portal (HELP) web-based system if no ophthalmologist in theatre.
3. Information to provide in consult:
   a. Focal history: Mechanism of injury, history of eyepro use, use of glasses or contact lenses
   b. Focal exam: Visual acuity, key exam findings
   c. Photograph(s)

PREVENTION

1. Encourage wearing only approved eye protection with MCEP, BPE, "eyepro," or "eye armor" (protective eyewear per Unit guidelines).
2. Discourage contact lens use.

Figures 1 & 2. Eye armor will help prevent many, but not all, eye injuries. If any kind of injury involves any portion of the face that would otherwise be covered by protective spectacles or goggles, maintain high level of suspicion – regardless of obvious severity.

Figure 1. Eye protection worked after vehicle hit by rocket-propelled grenade.

Figure 2. Maintain high index of suspicion for eye trauma injury even if not obvious.
Photo credit: COL (Ret) Thomas H. Mader, MD.

OPEN GLOBE INJURY

MECHANISM

- Laceration(s) from penetrating or perforating trauma. [13]
- Ruptured globe from blunt trauma.

EXAM FINDINGS

- Collapsed or severely distorted eye.
- Open wound, full-thickness corneal or scleral laceration.
- Shallow anterior chamber.
- Peaked or irregular pupil.
- Prolapse of intraocular contents outside the eye. Dark tissue is iris or uveal tissue.
- Subconjunctival hemorrhage (SCH), especially if 360 degrees.

MANAGEMENT [14-19]

1. Assess and document vision when possible.
2. Early teleophthalmology consultation with eye surgeon (See Teleophthalmology).
3. SHIELD AND SHIP
   a. Rigid eye shield immediately.
   b. Evacuation for urgent surgical repair within 24 hours when possible. [18,20-25]
4. Nothing to eat or drink.
5. Bed rest with head elevated 30 degrees if possible.
6. Avoid maneuvers that increase intraocular pressure.
7. Start systemic antibiotics. [14,26-34]
   a. Levofloxacin 750 mg IV/PO q24hrs PLUS Vancomycin 15-20mg/kg IV q8-12hrs OR
   b. Moxifloxacin 400 mg IV/PO q24hrs
   c. Preferred regimen for prophylaxis is levofloxacin plus vancomycin or moxifloxacin alone based on limited data, expert opinion, and spectrum of antibiotic activity; this provides coverage for *B. cereus*, gram negative organisms including *Pseudomonas aeruginosa*, and drug resistant gram positive organism such as MRSA. Note that vancomycin penetration into vitreous is limited in a healthy eye; weight based dosing may improve levels. Levofloxacin and moxifloxacin have excellent penetration. Levofloxacin has superior gram negative coverage and moxifloxacin has greater gram positive coverage. Either drug, when used alone, do not have reliable MRSA coverage.
8. Treat nausea and vomiting aggressively (Ondansetron 4-8 mg IV).
9. Administer tetanus prophylaxis per Infection Prevention in Combat-Related Injuries CPG.

10. Provide sedation and analgesia as needed (maintain patient comfort).
11. DO NOT put pressure on eye. It may increase the risk of extrusion of intraocular contents.
12. Do NOT attempt ultrasound of the eye. It places pressure on the eye.
13. Do NOT attempt to repair.
14. Do NOT attempt to enucleate eye.
15. Do NOT attempt to debride tissue, even if the eye is severely traumatized.

IOFB INJURY

HISTORY

High index of suspicion if blast injury, shrapnel, or metal-on-metal injury.

EXAM

- Penetrating or perforating site(s) sclera or cornea.
- Hole in iris.
- Findings may be subtle; maintain high index of suspicion

MANAGEMENT [37,38]

1. Assess and document vision if possible.
2. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
3. SHIELD AND SHIP
    a. Apply rigid eye shield immediately.
    b. Evacuate for urgent surgical repair within 24 hours if possible. [38-44]
4. Nothing to eat or drink.
5. Bed rest with head elevated 30 degrees if possible.
6. Avoid maneuvers that increase intraocular pressure.
7. Start systemic antibiotics. [38,40]
    a. Levofloxacin 750 mg IV/PO q24hrs PLUS Vancomycin 15-20mg/kg IV q8-12hrs OR
    b. Moxifloxacin 400 mg IV/PO q24hrs
    c. Preferred regimen for prophylaxis is levofloxacin plus vancomycin or moxifloxacin alone based on limited data, expert opinion, and spectrum of antibiotic activity; this provides coverage for *B. cereus*, gram negative organisms including *Pseudomonas aeruginosa*, and drug resistant gram positive organism such as MRSA. Note that vancomycin penetration into vitreous is limited in a healthy eye; weight based dosing may improve levels. Levofloxacin and moxifloxacin have excellent penetration. Levofloxacin has superior gram negative coverage and moxifloxacin has greater gram positive coverage. Either drug, when used alone, do not have reliable MRSA coverage.
8. Treat nausea and vomiting aggressively (Ondansetron 4-8 mg IV).
9. Administer tetanus prophylaxis per Infection Prevention in Combat-Related Injuries CPG.
10. Provide sedation and analgesia as needed.
11. ***Do not attempt to remove IOFB***.
12. ***Do not put pressure on eye***, it may increase the risk of extrusion of intraocular content.

Photo credit: CAPT (Ret) Joseph Pasternak, MD.

CHEMICAL INJURY

EXAM

1. Epithelial defect(s) of cornea or conjunctiva
2. Redness and swelling of conjunctiva
3. Blanching of conjunctiva
4. Corneal opacification

MANAGEMENT

1. Begin irrigation immediately.
    - Irrigate with normal saline or lactated Ringer's if available.
    - Acceptable to use water or any neutral irrigation solution (best solution choice is normal saline or lactated Ringer's).
    - Use Morgan Lens (first choice if available) or nasal cannula hooked to IV tubing for continuous irrigation. (See Continuous Irrigation Using Nasal Cannula.)
2. Use a **minimum of 2 liters** irrigation if unable to check PH. Some chemical injuries require up to 10 liters.
3. Apply topical anesthesia with tetracaine, proparacaine or lidocaine as needed to maintain patient comfort during irrigation.
4. Do NOT try to neutralize acid with base or base with acid.
5. Remove visible acidic or basic foreign bodies with a cotton tip applicator (CTA).
6. Remember to inspect the conjunctival fornices for retained foreign bodies. Irrigate or sweep fornices with a CTA.
7. Assess and document vision if possible.
8. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
9. SHIELD AND SHIP.

Figures: Chemical injury.

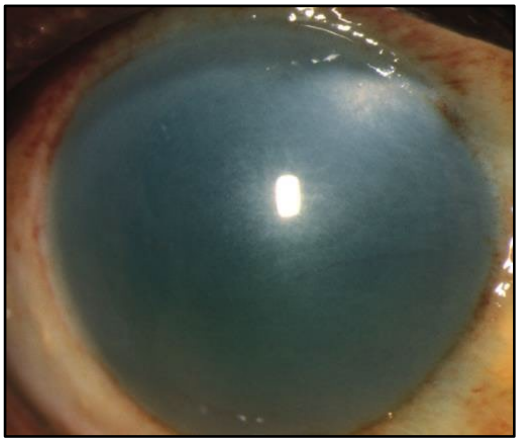

Figure 12. Irrigation. Using bottle of normal saline to irrigate the eye, patient is instructed to look in various directions while the opposite portions of the conjunctival cul-de-sac are flushed vigorously.
Photo credit: 2018 American Academy of Ophthalmology.

ORBITAL COMPARTMENT SYNDROME

HISTORY

Most common cause is **retrobulbar hemorrhage/orbital hemorrhage**.

EXAM

1. Decrease or loss of visual acuity.
2. "Rock hard" eyelids, or eyelids tight against the globe on palpation.
   Palpate eyelids to see if one eye has increased firmness and resistance compared with the opposite eye.
3. Proptosis: bulging of affected eye compared to the other.
4. Relative afferent pupillary defect (RAPD).

MANAGEMENT

1. Emergent lateral canthotomy and inferior cantholysis. (See Lateral Canthotomy.)
2. Assess and document vision if possible.
3. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology).
4. SHIELD AND SHIP.

HYPHEMA [45]

EXAM

- Blood or clot in anterior chamber.
- "8-ball" or "black ball" hyphema is blood filling the anterior chamber.

MANAGEMENT

1. Rule out open globe.[46]
2. Assess and document vision if possible.
3. Determine if the patient has sickle cell disease or trait.
4. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
5. SHIELD AND SHIP.
6. Bed rest with head elevated 30 degrees if possible.

Figure 13. Hyphema. Blood filling anterior chamber.
Photo credit: 2018 American Academy of Ophthalmology.

ORBITAL FRACTURE

EXAM

- Step-off orbital rim.
- Restricted eye movements.
- Enophthalmos (affected eye is further back in orbit compared with other eye).
- Hypoglobus (affected eye is lower compared with other eye).
- Subcutaneous or conjunctival emphysema.
- Numbness below eye.

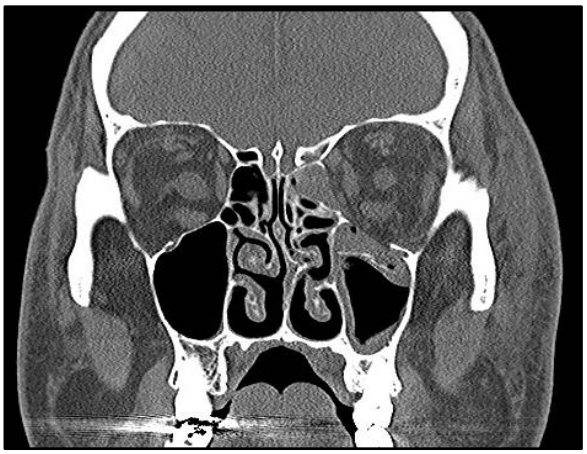
MANAGEMENT

1. Urgent repair required when clinical evidence of extraocular muscle entrapment with nonresolving bradycardia, heart block, nausea, vomiting, or syncope (oculocardiac reflex).
2. Assess and document vision if possible.
3. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology).
4. SHIELD AND SHIP.
5. Consider systemic antibiotics if sinusitis or dirty wound.
6. Avoid Valsalva and maintain sinus precautions (no nose blowing).
7. Maintain high suspicion for open globe.

Figures: Orbital fracture.

Figure 14. Entrapment of left inferior rectus muscle from left orbital floor fracture. Patient is unable to look upward with left eye.
Photo credit: Maj Brett Davies.

Figure 15. Computed tomography showing left orbital floor and medial wall fractures.
Photo credit: Maj Brett Davies.



EYELID LACERATION

EXAM

Note if laceration involves eyelid margin or nasolacrimal system.

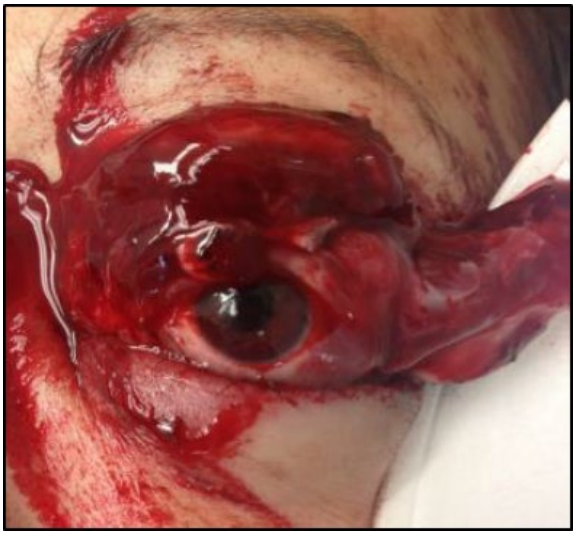
MANAGEMENT

1. Maintain high suspicion for open globe.
2. Assess and document vision if possible.
3. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
4. SHIELD AND SHIP.
5. Unless experienced, delay definitive repair for laceration involving eyelid margin for surgery by ophthalmologist. Do NOT repair in the presence of an open globe injury.
6. Do NOT debride or discard tissue, even if the eye is severely traumatized.

Figures: Eyelid laceration.

Figure 16. Lower eyelid laceration involving nasolacrimal system.
Photo credit: Maj Brett Davies.

Figure 17. Upper eyelid laceration.
Photo credit: Maj Brett Davies.



THERMAL BURN

EXAM

- Facial burn
- Eyelid burn and eyelash loss

MANAGEMENT

1. Assess and document vision if possible.
2. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
3. SHIELD AND SHIP.
4. If unable to close eyelids, start sterile eye ointment to prevent eye exposure.
   a. Give petrolatum or erythromycin ointment if available.
   b. Apply every 2-4 hours to eye surface.
5. Aggressive fluid resuscitation may rarely lead to orbital compartment syndrome requiring lateral canthotomy and inferior cantholysis.

Figure 18. Eye and facial thermal burn. Eye ointment on ocular surface.
Photo credit: Maj Brett Davies.

CORNEAL ABRASION

EXAM

- Epithelial defect.
- NO infiltrate (whitish opacity in cornea). Infiltrates indicate infection or inflammation of cornea.
- Stains with fluorescein when illuminated with cobalt blue light if available.

MANAGEMENT

1. Ophthalmic antibiotic ointment or drops.
    a. Erythromycin, bacitracin, or bacitracin/polymyxin one ribbon every 2-4 hours if available OR
    b. Fluoroquinolone (e.g., moxifloxacin, gatifloxacin, levofloxacin) OR polymyxin B/trimethoprim instill one drop 4 times daily if available.
2. Stop contact lens wear.
3. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)

Figures: Corneal abrasion.

Figure 19. Epithelial defect with NO infiltrate.
Photo credit: CAPT (Ret) Joseph Pasternak, MD.

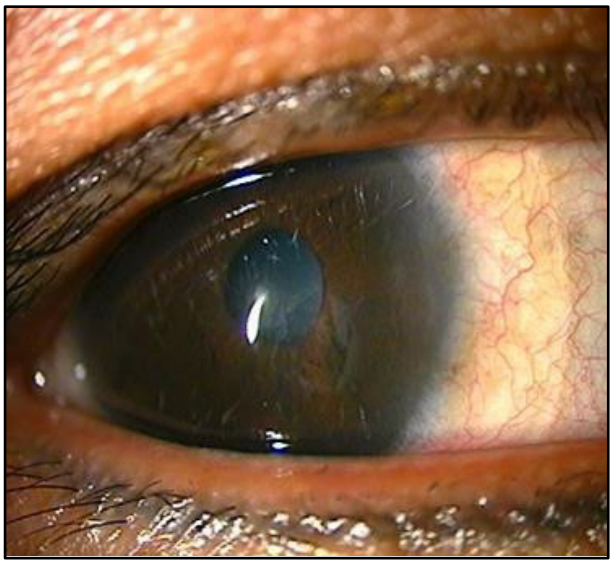


Figure 20. Epithelial defect stains with fluorescein when illuminated with cobalt blue light.
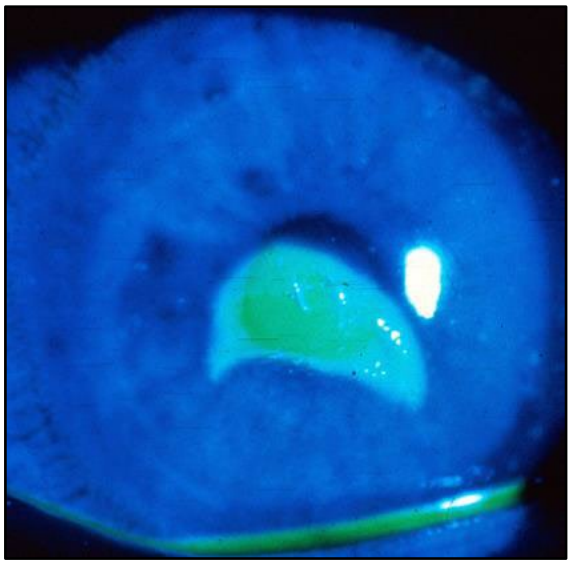
Photo credit: CAPT (Ret) Joseph Pasternak, MD.



INFECTIOUS KERATITIS / CORNEAL ULCER

These conditions are commonly associated with contact lens wear or overuse. Numerous regulations prohibit or limit wear during deployment, but contact lens use during deployment continues to be common.

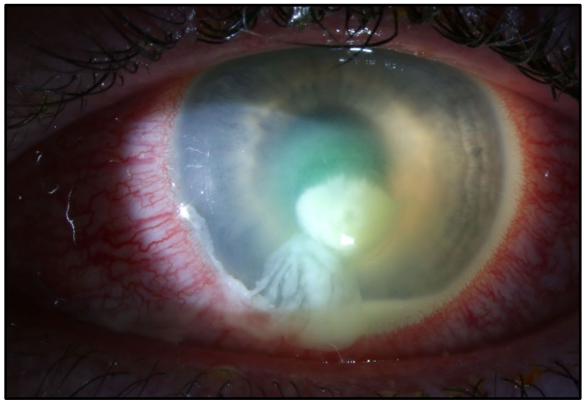
EXAM

- Epithelial defect
- Corneal infiltrate (whitish opacity in cornea)

MANAGEMENT

1. Assess and document vision if possible.
2. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology).
3. SHIELD AND SHIP.
4. Stop contact lens wear.
5. Start topical antibiotic drops if available. Instill one drop every hour while awake.
   Give fluoroquinolone (i.e. moxifloxacin, gatifloxacin, levofloxacin) OR polymyxin B/trimethoprim if available.

Figure 21. Pseudomonas infectious keratitis (corneal ulcer) from contact lens wear.
Photo credit: Lt Col Chantal Cousineau-Krieger.



CORNEAL AND CONJUNCTIVAL FOREIGN BODIES

EXAM

- Corneal or conjunctival foreign body
- If metallic, there may be a rust ring

MANAGEMENT

1. Superficial foreign bodies may be irrigated away or removed with a moistened CTA under topical anesthesia (proparacaine or tetracaine drops).
2. Start topical ophthalmic antibiotic drops or ointments if available.
3. Do NOT remove impaled or resistant foreign bodies.
4. Assess and document vision if possible.
5. Teleophthalmology consultation with eye surgeon.
6. SHIELD AND SHIP.

Figure 22. Corneal metallic foreign body.
Photo credit: © 2018 American Academy of Ophthalmology.

INTRAORBITAL FOREIGN BODY

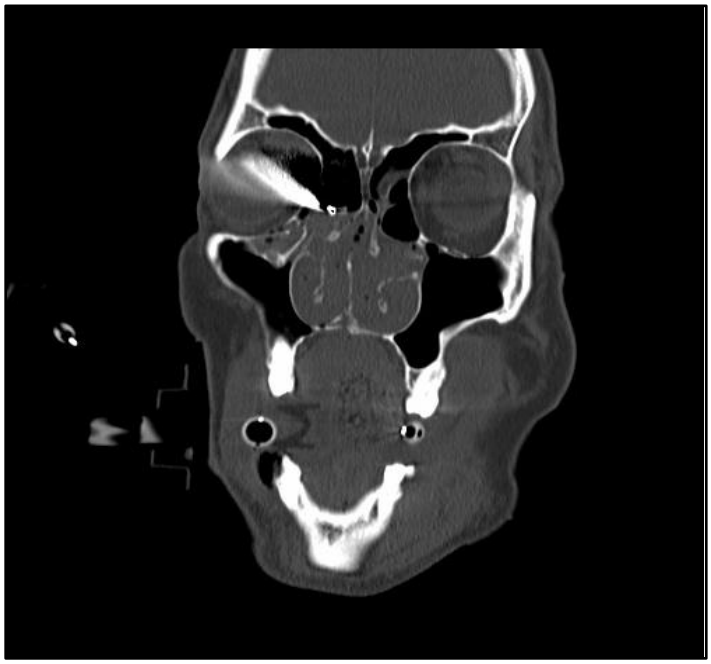
EXAM

Intraorbital foreign body visible on examination or identified on diagnostic imaging such as X-ray or CT.

MANAGEMENT

1. Do NOT remove impaled or resistant foreign bodies.
2. Assess and document vision if possible.
3. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
4. SHIELD AND SHIP.

Figure 23. Intraorbital foreign body. Bullet in right orbit.
Photo credit: LTC Won Kim.



LASER EXPOSURES [47,48]

1. Assess and document vision.
2. Report incident to supervisor.
3. Follow the recommendations outlined in *JTS CPG Ocular Evaluation and Disposition after Suspected Laser Exposure*.[49]

LASIK FLAP DISLOCATION

1. Do NOT amputate.
2. Assess and document vision if possible.
3. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
4. SHIELD AND SHIP.

TRAUMATIC OPTIC NEUROPATHY

HISTORY

Vision loss after eye trauma

EXAM

- Decreased visual acuity
- Afferent pupillary defect

MANAGEMENT

1. Assess and document vision and afferent pupillary defect.
2. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
3. SHIELD AND SHIP.

ANGLE-CLOSURE GLAUCOMA

HISTORY

Blurred vision or loss of vision, halos around lights, severe eye pain, severe headache, eye redness, nausea and vomiting.

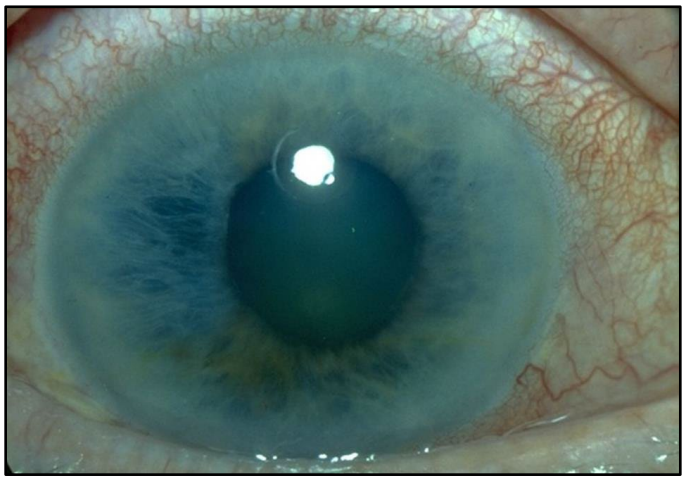
EXAM

- Palpate eyelids to see if involved eye has increased firmness compared with the opposite eye.
- Fixed, mid-dilated pupil.
- Shallow anterior chamber.
- Corneal edema (hazy cornea).
- Conjunctival injection.

MANAGEMENT

1. Assess and document vision if possible.
2. Teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
3. Give acetazolamide 500 mg PO initial dose, then 250 mg PO every 4 hours to decrease IOP if available.
4. Start intra ocular pressure (IOP)-lowering topical medications if available.
   Instill 1 drop of timolol, brimonidine, and dorzolamide 5 minutes apart. Repeat for 3 rounds.
5. SHIELD AND SHIP.

Figure 24. Acute angle closure glaucoma.
Photo credit: LTC Won Kim.



PRESEPTAL CELLULITIS

EXAM

- Eyelid redness, swelling, tenderness, and warmth.
- Usually little or no swelling or redness of conjunctiva.
- NO signs of orbital involvement including restriction of eye movement, pain with eye movement, proptosis (eye bulging forward), loss of vision, or afferent pupillary defect.

MANAGEMENT

1. Assess and document vision if possible.
2. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
3. Start oral antibiotics
   Clindamycin 300 mg PO q8hrs OR Amoxicillin-clavulanic acid 875 mg PO q12hrs if available.
4. SHIELD AND SHIP.

Figure 25. Preseptal Cellulitis.
Photo credit: Maj Brett Davies.

ORBITAL CELLULITIS

EXAM

- Eyelid redness, swelling, tenderness, and warmth.
- Swelling and redness of conjunctiva.
- Signs orbital involvement may include restriction of eye movement, pain with eye movement, or proptosis (eye bulging forward), loss of vision, or afferent pupillary defect.

MANAGEMENT

1. Assess and document vision if possible.
2. Obtain urgent CT head and orbits as soon as possible to determine if there is an abscess that needs to be surgically drained.
3. Seek teleophthalmology consultation with eye surgeon. (See Teleophthalmology.)
4. Start broad-spectrum IV antibiotics if available.[50]
    - Ampicillin-sulbactam 3 g IV q6 hours OR piperacillin-tazobactam 4.5 g IV q6 hours PLUS
    - Vancomycin 15-20 mg/kg IV per dose q8-12 hours, maximum 2 g for each dose.
5. SHIELD AND SHIP.

Figure 26. Orbital Cellulitis. Sight-threatening infection of the right orbit.

PROTECTIVE EYEWEAR

1. Prevent eye injuries.
   a. Encourage wearing only approved eye protection – eyepro or eye-armor.[51-53]
      - MCEP
      - BPE
   b. Discourage contact lens use.
2. Look for the "APEL" label.
   a. Army's Program Executive Office – Soldier (PEO-Soldier) certifies all MCEP items to meet or exceed safety and ballistic fragmentation standards.
   b. Approved eyewear found on the APEL, available at http://www.peosoldier.army.mil/equipment/eyewear/
   c. APEL eyewear is identifiable by a neon green "APEL" logo required to be on all MCEP packaging and the "APEL" name permanently marked on the frame (located on left temple or strap).
   d. APEL eyepro comes in spectacle and goggle designs and in various sizes, with optical inserts available for some models.
   e. Service-specific policies may influence or limit the availability and variety of APEL eyepro.

f. APEL eyewear should NOT be assumed to be sufficient for occupational tasks where specific safety eyewear is required (welding, chemical protection, splash protection, or other OSHA-specified tasks).

g. Many commercial manufacturers produce "MIL-SPEC" polycarbonate eyewear, but only a few models pass the rigorous additional testing requirements.

- Many candidate models fail because of frame failure rather than lens failure.
- CAUTION: "Meets or exceeds MIL-SPEC" does not mean the model has passed APEL testing.
- Be particularly vigilant and cautious when ordering eyewear or replacement eyepro online.
- Counterfeit eyepro has surfaced in theater; beware of "bargain" eyepro. When purchasing eyepro, look for the official "APEL" marks and tags.

Figures 27, 28, 29: APEL labeling. U.S. Army Photo by PEO Soldier.

Figure 27. Neon green APEL logo required on MCEP packaging.

Figure 28. APEL eye gear.

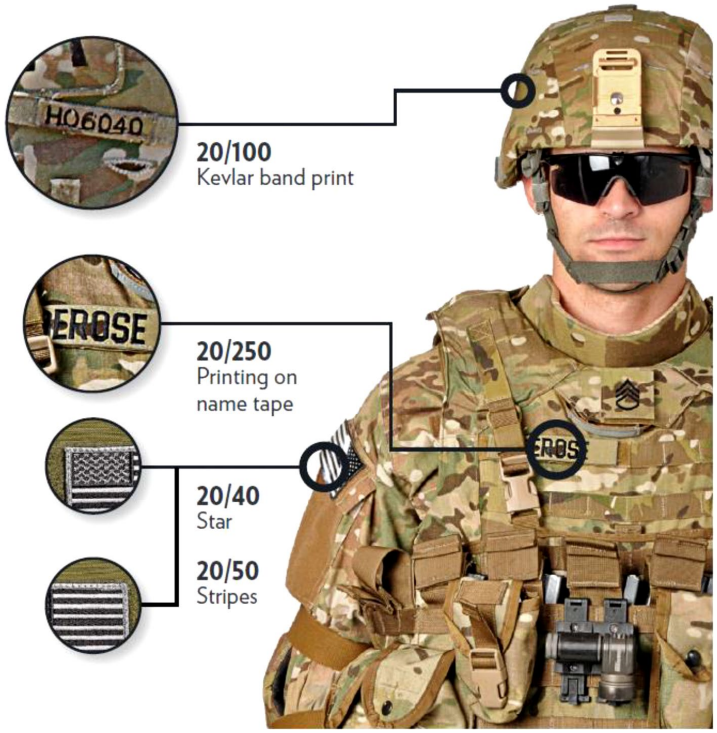
Figure 29.APEL name permanently marked on eye gear frame.

VISUAL ACUITY TESTING [8]

1. Some patients may require drop of topical anesthetic to tolerate testing.
2. Decide upon testing method.
3. Place the patient at the designated testing distance.
   a. Use Snellen eye chart if available. Start testing at 20 feet. Move patient closer if unable to see letters. Can move patient as close as 3 feet to chart.
   b. Letters and patches on the uniform can be used in the field. (See Figure 30 below.) Testing distance is 3 feet .[54]
   c. If patient is unable to see letters or patches, use the testing methods below:
      - Count fingers: Hold up one hand, extend one or more fingers and ask the patient to count the number of fingers. Record the greatest distance from the patient at which counting fingers is done accurately.
      - Hand motion: Hold up one hand and wave one hand. Record the greatest distance from the patient at which the patient can detect movement of your hand.
      - Light perception: Use a penlight or other bright light source and shine in the eye. Record the patient's response as light perception if able to detect the light. Record the patient's response as no light perception if unable to detect the light. Record the light source used for testing (e.g. penlight or flashlight).

4. Test with patient wearing glasses if available.
5. Record whether testing completed with or without glasses correction.
6. Test the right eye first by convention. Completely cover the left eye using the palm of your hand.
7. Do NOT put pressure on eye with suspected open globe injury.
8. If testing using letters, ask the patient to read the smallest line in which he or she can distinguish more than half the letters.
9. Record the acuity measurement as a notation (example 20/20) in which the numerator represents the distance at which the test is performed and the denominator represents the numeric designation for the line read.
10. Repeat the procedure for the other eye.
11. Record visual acuity for both eyes.
12. Example # 1
    - Right eye: uniform name tape 3 feet without correction.
    - Left eye: count fingers 2 feet without correction.
13. Example # 2
    - Right eye: hand motion 2 feet with glasses.
    - Left eye: stripes U.S. Flag patch 3 feet with glasses.

Figure 30. Visual Acuity Testing.
Letters and patches on a U.S. Army uniform that can be used to determine visual acuity in the field. If using this method, test from a distance of 3 feet. *Photo credit: Vision Center of Excellence.*



RAPD TESTING

1. Useful in the evaluation of unilateral or asymmetric vision loss, even in an unconscious patient.
2. "Swinging flashlight test" technique.
   a. Use bright light source such as penlight or flashlight for testing.
   b. If patient is able to follow commands, have patient fixate on a distant object.
   c. Shine light into one eye and note the pupillary response.
   d. Swing the light quickly to the opposite eye and note the pupillary response.
   e. Swing the light quickly back to the first eye while maintaining the same distance from each eye.
3. Normal response: Pupils constrict simultaneously and equally in response to light in either eye (consensual light reflex).
4. Abnormal response: When swinging light to the injured or diseased eye, both pupils constrict less or dilate (positive relative afferent pupillary defect or Marcus Gunn pupil).

HOW TO PLACE EYE SHIELD

1. Use rigid eye shield.
   - Fox shield if available. (See Figure 31a.)
   - Can use member's own eye protection if intact or minor damage. (See Figure 31b.)
   - Other rigid materials that do not place pressure on the eye can be used as an eye shield - like a cup. (See Figure 31c.)
2. Position shield so rim of the orbit supports it when taped.
3. Secure shield with tape. Recommend 3 strips or enough to secure.
4. Shield ONLY injured eye. Shielding both eyes increases patient anxiety.
5. DO NOT patch. It puts pressure on eye. (**DO shield but DO NOT patch**).
6. Do NOT wrap. It puts pressure on eye.
7. Do NOT place anything under an eye shield including gauze.

Figure 31. Eye shields.

Figure 31a. Fox shield.

Figure 31b. Can use member's own eye protection if intact or minor damage.

Figure 31c. Other rigid materials as eye shield. Materials do not place pressure on the eye can be used as an eye shield - like a cup.

CONTINUOUS IRRIGATION USING MORGAN LENS

SUPPLIES NEEDED USING MORGAN LENS

1. Topical anesthetic (0.5% Proparacaine or 0.5% Tetracaine)
2. Morgan Lens
3. IV tubing set and IV pole
4. Irrigating solution – best solution choice is normal saline or lactated Ringer's
5. Fluid collection equipment (basins, bowels, or MorTan Medi-Ducts)
6. pH paper or urine dipstick strips

STEPS USING MORGAN LENS[55]

Figures 32A. Continuous irrigation using Morgan Lens[55]
Source: Images reprinted from Morgan Lens Instructional Chart. Courtesy of Morgan Lens, MorTan Inc.

Step 1. Figure 32A-1. Instill topical anesthetic to traumatized eye(s).

Step 2. Figure 32A-2. Connect 1/2 Morgan Lens to delivery IV tubing set.

Step 3. Figure 32A-3. Start minimal flow of irrigation solution.

Step 4. Figure 32A-4. Insert Morgan Lens. Have patient look down. Retract upper eyelid. Insert lens under retracted upper eyelid. Have patient look up. Retract lower eyelid. Insert lens under lower eyelid. Instruct patient to keep eye(s) closed.

Step 5. Figure 32A-5. Adjust fluid flow, tape lines to forehead of patient, place fluid collection equipment.

Step 6. Figure 32A-6. Remove Morgan Lens. After neutral pH point achieved (pH 7.0 to 7.5), stop fluid flow to instill topical anesthetic, then restart fluid flow. Have patient look up and retract.

CONTINUOUS IRRIGATION USING NASAL CANNULA

SUPPLIES NEEDED

1. Topical anesthetic (0.5% Proparacaine or 0.5% Tetracaine)
2. Irrigating solution – best solution choice is normal saline or lactated Ringer's
3. IV pole
4. Pressure infuser
5. IV tubing
6. Nasal cannula
7. Connection between IV tubing and nasal cannula tubing. (See Figure 32B-2).
   - Tubing connector
   - Stopcock connector
   - Syringe tip cap (cut off top with scissors)
8. Irrigating solution – best solution choice is normal saline or lactated Ringer's.
9. Fluid collection equipment (basins, bowels, or MorTan Medi-Ducts)
10. pH paper or urine dipstick strips

STEPS

1. Instill topical anesthetic to traumatized eye(s)
2. Hang IV fluid on IV pole inside pressure infuser.
3. Spike and prime IV tubing.
4. Connect IV tubing to nasal cannula tubing.
5. Position nasal cannula on forehead so prongs provide continuous irrigation into both eyes.

6. Run continuous irrigation wide open until neutral pH point achieved (pH 7.0 to 7.5)

Figure 32a-c. Continuous irrigation for chemical injury using nasal cannula.

Figure 32a. Normal saline or lactated ringers inside pressure infuser.

Figure 32b. Connectors can be used to connect IV tubing and nasal cannula tubing (left to right): tubing connector, stopcock connector, syringe tip cap (cut off top with scissors).

Figure 32c. Position nasal cannula on forehead so prongs provide continuous irrigation into both eyes.

LATERAL CANTHOTOMY AND INFERIOR CANTHOLYSIS

1. If possible, give subdermal injection of lidocaine 2% with epinephrine to the lateral canthus. It can be difficult to inject tissue that is already swollen.
2. Optional only if good local anesthesia. Apply a hemostat or needle driver horizontally at the lateral canthus for 1 minute to reduce bleeding.
3. Perform lateral canthotomy.
   Use blunt scissors to incise the lateral canthus, FULL THICKNESS, for 1-2 cm to the lateral bony orbital rim (canthotomy).
4. Perform inferior cantholysis:
   a. With toothed forceps, grasp the lower eyelid firmly at the edge of the incised canthus (at the orbital rim) and apply traction away from the eye.
   b. Keeping one scissor blade behind the lid (in the conjunctival fornix) and one blade over the skin, angle the scissors toward the corner of the mouth or nasal ala. Make a FULL THICKNESS cut across the lower lid for length of 1-2cm. This should fully disinsert the lid. You may be able to palpate or “strum” the inferior part (inferior crus) of the lateral canthal tendon as a “guitar string” before cutting.
   c. If successful, the eyelid should swing freely and come completely away from the globe. If the eyelid remains in its normal position, use scissors tips to feel for residual tethering bands, and continue cutting until the lid swings freely.
   d. There may not be a “gush of blood” even with successful release.

5. Recheck vision and intraocular pressure. If the intraocular pressure remains elevated with poor vision and a tense orbit, then perform superior cantholysis, separating the upper lid from the orbital margin. Also consider giving 500MG IV acetazolamide.

AEROMEDICAL EVACUATION CONSIDERATIONS

Due to the requirement to move the coalition patient with vision-threatening injuries to a Role 3 with an ophthalmologist in theater or Role 4 outside the area of responsibility (AOR), early and safe transport of these patients should involve consideration of several factors.

1. Initiate teleophthalmology consultation with an ophthalmologist as soon as possible.

2. Management of concomitant injuries is crucial during flight.

3. After open globe injury, rotary wing aeromedical evacuation may be accomplished in theater without prior clearance by an ophthalmologist.

4. Teleophthalmology consultation with an ophthalmologist is recommended before fixed wing transport of an open globe injury. Typically the patient is cleared for immediate transport. If available, CT imaging of the orbit with thin slices can identify if there is trapped intraocular air, which could cause an acute rise in intraocular pressure or extrusion of intraocular contents in a depressurized cabin. In this situation, the aircraft commander should be notified that the internal cabin pressure should be maintained between sea level and 2500 feet to keep gas expansion at or below 10%. The aircraft commander can determine a safe aircraft altitude for that mission based on that information. For example, if the transport aircraft is a C-17, cabin altitude can be up to 2500 feet and allow the aircraft to fly safely at 24,000 feet.

5. Vibration and turbulence can also be increased during flight. Adequate immobilization of foreign bodies to prevent further injury. Pain related to traumatic injuries is exacerbated by vibration and adequate pain medication is required.

6. Decreased visual input will increase the risk of motion sickness. Vomiting can increase the risk of further injury. Anti-emetics can help to mitigate this risk.

7. The need to Valsalva or perform similar maneuvers to equalize middle ear pressure can further injure the eye and surrounding structures, particularly the inferior orbit which overlies the maxillary sinuses. Adequate rapid acting decongestants (i.e. Afrin) can be used.

8. Air handling systems on board the aircraft result in a very low relative humidity. Generous use of medications to lubricate the eye may be necessary.

9. Patients with eye injuries cannot generally safely navigate inside aircraft due to poor lighting and cramped space and decrease in visual cues to balance. Consider placing the patient on a litter for safety and a non-medical attendant to help patient move if needed.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

- All patients with diagnosis of eye injury.
- All patients with a diagnosis of retrobulbar hematoma or orbital compartment syndrome.

INTENT (EXPECTED OUTCOMES)

1. All patients in populations of interest have visual acuity tested and documented in both eyes at all roles of care (including point of injury). If the patient is unresponsive or intubated and sedated this is documented and the pupils are checked for a relative afferent pupillary defect.
2. All patients in populations of interest have a rigid eye shield placed correctly and documented at all roles of care (including point of injury) that do not have an ophthalmologist.
3. All patients with open globe injuries receive appropriate antibiotics at the first role of care.
4. All patients with a diagnosis of retrobulbar hematoma or orbital compartment syndrome receive an immediate full thickness lateral canthotomy and inferior cantholysis.
5. All patients in populations of interest receive a teleophthalmology consultation.
6. All patients in population of interest with vision-threatening injuries are evacuated so that they are able to receive treatment by an ophthalmologist within 24 hours. If evacuation is not possible, the reason for the delay is documented.

PERFORMANCE / ADHERENCE MEASURES

1. Number and percentage of patients in the populations of interest that have visual acuity tested and documented in both eyes.
2. Number and percentage of patients in the populations of interest who have rigid eye shield placed correctly and documented at all roles of care (including point of injury) that do not have an ophthalmologist.
3. Number and percentage of patients with open globe injury who receive appropriate antibiotic at the first role of care.
4. Number and percentage of patients with a diagnosis of retrobulbar hematoma or orbital compartment syndrome who receive an immediate full thickness lateral canthotomy and inferior cantholysis.
5. Number and percentage of patients in the populations of interest who receive a teleophthalmology consultation.
6. Number and percentage of vision-threatening injuries that are evacuated so that they are able to receive treatment by an ophthalmologist within 24 hours. If evacuation not possible, the reason for the delay is documented.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Chief, JTS Program Manager, and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Frostbite and Immersion Foot Care (CPG ID: 59)

This CPG provides an overview of cold injuries and presents a standardized approach to providers in the evaluation and treatment of patients with cold injuries including the role of intravascular therapy

BACKGROUND

Historically, cold Injury, hypothermia and frost bite have been a severe problems for military units on the battlefield.[1] While not common in modern conflicts, the potential exists for large numbers of these casualties in war and during training.[2,3] Cold injury requires two things: a low absolute temperature and an exposure duration. In general, the human body contains the mechanisms to preserve core body temperature and extremities even if limb perfusion is temporarily impeded in order to preserve core body temperature. When these mechanisms are overwhelmed, the result is permanent tissue damage. The ultimate mechanism of injury involves a combination of direct cold injury to the cells, direct intracellular and intercellular ice formation, ischemia from thrombosis of the vasculature, and reperfusion injury.[4] The patients that are afflicted with cold injury generally fall into one of two categories: those involved in industrial accidents and those unable to escape their environment. Patients in the military predominantly will fall into the category of inability to escape the environment. Unlike other types of injuries, all forms of cold injury are potentially preventable with knowledge, equipment, and foresight. Acclimation to the environment provides some protection while those of African descent have increased susceptibility to cold injuries.[5]

Increased rates of frostbite occur at extreme high altitude secondary to ambient temperature decreases and microcirculatory changes that occur at altitudes greater than 17,00ft.[6,7]

EVALUATION

TRAUMA EVALUATION

All patients with identified cold injury should be considered trauma patients first to identify other life threatening injuries. If possible, attempt to establish the circumstances which led to prolonged environmental cold exposure. In addition, patients are likely hypothermic and should be warmed expediently before focusing on cold injuries of the extremities. In the field, cold extremities may be warmed as a consequence of treating a hypothermic patient. It is imperative to prevent refreezing of the impacted extremity as it results in more tissue damage.

COLD INJURIES

Cold injury is not a single diagnosis but rather a spectrum with all categories possibly present on a single extremity, the most distal portion usually being the most severely affected. Normothermia must be established prior to making the diagnosis of cold injury. Many people experience numbness of extremities with prolonged cold exposure with return to normal function without any permanent damage; this in isolation, will not result in cold injury. Cold injury has occurred when upon re-warming there is pain and swelling or gross signs of ischemia or skin injury. There are classically four degrees, with depth of injury distinguishing the different degrees:

First Degree: Superficial skin injury; pain on re-warming, numbness, hyperemia, occasional blue mottling, swelling and superficial desquamation (desquamation starts at about 5 days)

Second Degree: Partial thickness injury to skin; in addition to first degree findings, vesiculation of the skin surrounded by erythema and edema (appears around day 2)

Third Degree: Entire thickness of skin extending into subcutaneous tissue; bluish to black and non-deformable skin, hemorrhagic blisters, vesicles may not be present, eventual ulcerations can be expected; area will likely be surrounded by 1st or 2nd degree injury

Fourth Degree: Similar to third degree, but full thickness damage including bone. Area may be cold to touch and may feel stiff or woody.

Another way to classify is superficial (First and Second Degree) and full thickness (Third and Fourth Degree) similarly to burns. The ultimate grade will not be truly known until treatment has been attempted and a period of time has passed.

There are very mild cold injuries labeled as Chilblains and Frostnip that do exist, but for the sake of caution in the field, the recommendation is to treat all acute presentations as first degree (superficial) frostbite as there is no morbidity in correcting hypothermia and rapid rewarming of suspected areas. Chilblains is a chronic condition, like a dermatitis, and if continues after initial treatment cold avoidance and supportive care can be provided.

IMMERSION FOOT

Commonly known as trench foot, it is a syndrome related to prolonged exposure to moisture. Classically it has been associated with cold water, but can happen in all climates. The syndrome generally happens slower in warm water, taking approximately 48 hrs, than cold water (earliest estimate 12 hours).

The clinical presentation is water logging of the feet, most pronounced in the soles. With continuous exposure, the foot becomes hyperemic, mottled, painful and edematous, gradually progressing into blistering, hypoperfusion, ulceration and gangrene.[8,9]

TREATMENT

COLD INJURY/FROSTBITE

Rapid Re-warming and Re-establishment of Perfusion

The mainstay of treatment of the cold injury is re-warming. **Rapid active re-warming is done in 104-108°F (40-42°C) water for 15- 30 minutes** as long as care can occur in an environment where there is no risk of refreezing. The temperature is important, as there is reduced effect with cooler temperatures and higher temperatures will cause burns. Passive re-warming or dry heating is not considered acceptable, but may be the only option depending on the operational environment and involves using body heat and blankets; always attempt to move the casualty safely to a warmer environment. Do not use blow driers, space heaters, or the like as these will cause burns. The goal is complete thawing and maximum perfusion as evidenced by hyperemia, swelling, and pain.[10] Rubbing the affected areas is to be avoided as this will further traumatize the skin**. The re-warming process can be expected to be very painful and narcotic and non-steroidal medications, including Ibuprofen/Aspirin and/or Ketamine should be utilized liberally.** It is tempting to re-warm slowly because this is better tolerated but tissue survival is improved with rapid re-warming. Pain usually subsides in approximately 3 days but prolonged aches, shooting pains, and throbbing can be expected for weeks.[1] Early surgical consultation should be made. Rapid re-warming can be conducted at point of initial care, but early evacuation to definitive care should be considered at the earliest available time. It is also very important that when rapid re-warming is done, it is to be completed, as refreezing after partial thawing will result in more severe injury.

During the course of treatment, patients should be prohibited from using any tobacco and nicotine-containing products as well as any medications inducing vasoconstriction. The limb should be elevated to reduce swelling. After re-warming, electrolyte abnormalities and rhabdomyolysis can occur. Electrolytes should be monitored every 6 hours initially, until normalized. Scheduled ibuprofen (400 mg PO every 6 hours) should be considered, with narcotics utilized for refractory pain. Sympathectomy and vasodilators have been attempted in studies, but there is insufficient evidence that these modalities improve outcomes and should not be routinely attempted. If available, hyperbaric oxygen can be considered and started between day 5 and 10.[4] Evidence for the use of systemic prophylactic antibiotics is lacking and is not recommended. Regular application of topical aloe vera

may help limit tissue loss.[4] After resolution of edema, whirlpool therapy combined with exercise can help maximize functional recovery of the extremity.

Photo documentation at point of injury when feasible can assist in continuum of care.

Thrombolytic Therapy

Care must be made to ensure patients are candidates for Tissue Plasminogen Activator (tPA) prior to therapy (see below). Patients should be within 24 hours of the start of injury. Patients should have evidence of severe frostbite as well as circulatory compromise as demonstrated by decreased or absent pulses, lengthened capillary refill, and/or ischemic discoloration of distal digits.[11]

Candidates for tPA:

- Within 24 hours of start of injury.
- Evidence of injury with vascular compromise.

Relative contraindications to tPA for frostbite injury include:

- Concurrent trauma.
- Recent surgery or hemorrhage.
- Bleeding diathesis.
- Cold contact injury without frostbite injury.
- Greater than 24 hours of ischemia.
- Evidence of freeze-thaw-freeze injury.

Patients that are being considered for therapy should be taken for diagnostic arteriogram of the affected extremity. If perfusion is compromised, papaverine, a vasodilator, may be introduced intraarterially at a rate of 30 mg/hr to decrease local vasospasm. Intraarterial tPA should be administered through the arterial catheter as follows: 2-4 mg bolus followed by a continuous infusion of 0.5-1.0 mg/h into the extremity. If multiple extremities are involved, arterial catheters are positioned in each extremity. The maximum dose of tPA would then be divided amongst the number of extremities. For example, if two extremities are involved, the maximum rate for each extremity is 0.5 mg/h. In addition, intraarterial heparin should be administered through the arterial sheath at a rate of 500 units/h to prevent new clot formation and extension of existing thrombi. Serial labs including PTT, fibrinogen, Hgb/Hct, and platelets are repeated every 6 hours. There is no PTT goal as the dose is small for a normal-sized adult. Angiograms are to be repeated every 8 to 12 hours to evaluate response to therapy. Termination of therapy is recommended to end with complete perfusion or at 48 hrs, unless complications from tPA occur or fibrinogen levels fall below 150. Patients should be closely monitored for hemorrhagic complication, neurologic, and cardiovascular complications from the tPA. If a patient develops serious bleeding complications, the tPA and heparin should be discontinued. If revascularization has occurred, and final cessation of tPA is made, heparin should be continued for at least 72 hours.[11,12]

A systemic, intravenous approach to tPA administration is available, but only with the ability to perform technetium scanning to confirm vascular compromise and response to therapy. The systemic approach is administration of a tPA bolus of 0.15 mg/kg intravenously followed by a 0.15 mg/kg/hr infusion over the next 6 hours to a maximum dose of 100 mg. After completion of tPA, heparin is started with a goal of two times normal control and is continued until conversion to Coumadin. Anticoagulation with Coumadin should be continued for 4 weeks.[13]

tPA should be avoided in a setting that lacks the ability to monitor and treat bleeding complications.

DEBRIDEMENT

Major surgical debridement, should not be performed in the operational environment for US Military or casualties that can be evacuated. Early excision is not part of the therapy for frostbite. Excision should be delayed until margins of injury are fully demarcated; this may take months. For minor injuries, local wound care can be performed with the addition of topical antibiotic and aloe vera gel or a sterile topical emollient every 6 hours. Wound care should be performed BID and sterile non-adherent dressing should be applied. Vesicles from second degree become dry, black, and hard in approximately 2 weeks and will generally peel away at 3-4 weeks.

Third degree frostbite forms an eschar and can be debrided in approximately 2-8 weeks depending on severity of the injury. There will be an ulcer and this will take further time to heal. The surrounding skin is easily traumatized from second degree frostbite.

With fourth degree frostbite, the mummification of the extremity or digit will become readily apparent in approximately 2 weeks. Most will continue the mummification process without sequelae and this should be a minimally painful process, but throbbing, shooting pains, and potentially severe aching can be expected for up to a month. Some moisture and purulence can be expected without significant concern unless signs of local or systemic sepsis present. The level of debridement/amputation can be delayed until mummification is complete.

For cases of full thickness injury (third and fourth degree) with infection, debridement and possible amputation are to be conducted expediently.

In general, surgical debridement should be done at a definitive care site outside of theater.

SUPPORTIVE CARE

Cold injury may have permanent symptoms after the injury. It is common to have patients with minimal injuries complain of persistent coldness, pain, and hyperhidrosis of the affected extremity. In addition, second degree frostbite will likely have intact, but easily damaged, skin. In many cases, patients are more susceptible to future cold injury which frequently is more severe than the initial insult.

Basic treatment for persistent side effects includes nonsteroidal analgesics and antiperspirants. These should be available at forward operating locations until further definitive dermatologic and surgical care can be provided.[14]

Mild injury can be managed at site of injury but any full thickness injury should be evacuated.

Tetanus booster should be provided based on immunization history.

IMMERSION FOOT

Similar to frostbite, re-warming of the extremity is required. This is done by **air drying at room temperature**. Pain control may be required along with debridement. Prophylactic antibiotics have not been shown to result in improved outcomes, but if concerned that infection is present, treatment should target streptococcal, staphylococcal, and *P aeruginosa* based on local antibiogram while awaiting any available cultures.[9] Similar to other cold injuries, persistent life altering symptoms can persist.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients diagnosed with cold injury (frostbite) or immersion foot.

INTENT (EXPECTED OUTCOMES)

1. Patients with diagnosis of frostbite have rewarming of affected extremities with 104-108°F (40-42°C) water.
2. Patients with severe cold injury (frostbite with tissue necrosis) AND who undergo rewarming within 24 hours of the start of cold injury receive TPA, unless documented contraindication.
3. Patients with immersion foot have dry heat administered.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who have documentation of treatment with water heated to 104-108°F (40-42°C).
2. Number and percentage of patients with severe cold injury (frostbite with tissue necrosis) AND who undergo rewarming within 24 hours of the start of cold injury who receive TPA.
3. Number and percentage of patients with severe cold injury (frostbite with tissue necrosis) AND who undergo rewarming within 24 hours of the start of cold injury who receive TPA or have a contraindication documented.
4. Number and percentage of patients with immersion foot who have documentation of dry heat administered.

DATA SOURCE

- Patient record
- Department of Defense Trauma Registry (DODTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

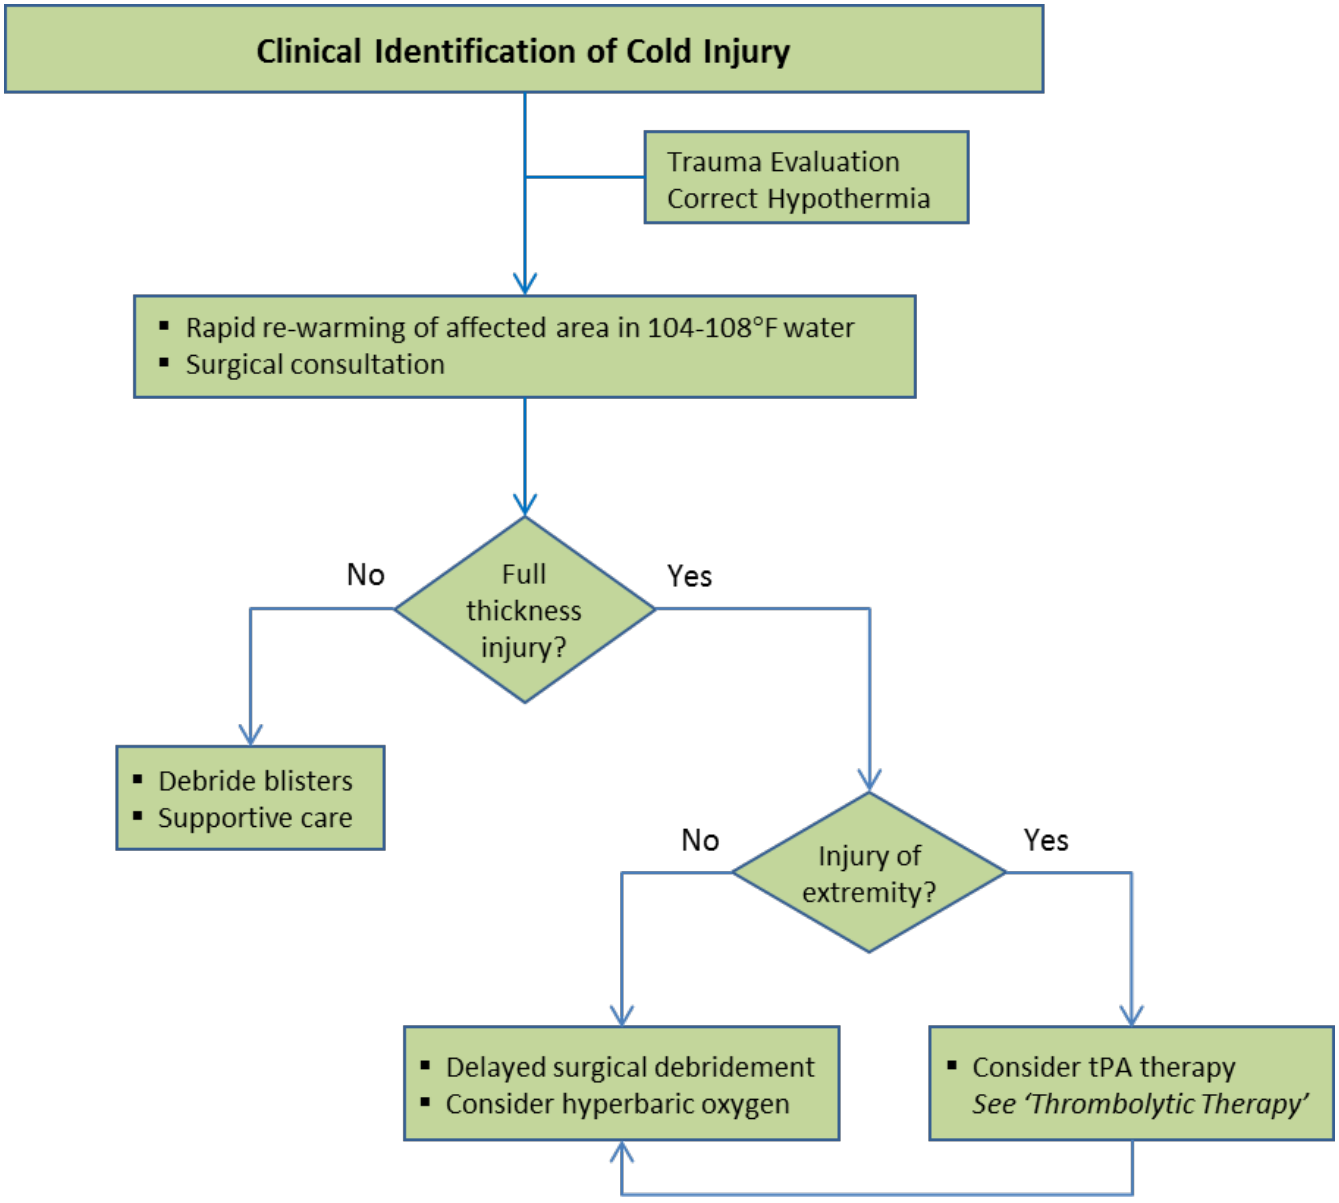
APPENDIX A: CLINICAL IDENTIFICATION OF COLD INJURY



APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

Appendix A: Massive Transfusion with DRBC compared to Standard Massive Transfusion 5
Appendix B: Additional Information Regarding Off-Label Uses in CPGs 6

BACKGROUND

Deglycerolized Red Blood Cells (DRBCs) are derived from 450-500 ml of whole blood collected in Citrate/Phosphate/Dextrose (CPD) or Citrate/Phosphate/Dextrose/Adenine (CPDA-1) collection bags. DRBCs can also be made from additive solution Red Blood Cell (RBC) units such as CPD/AS-1, CPD/AS-5 or CP2D/AS-3 if these are first centrifuged to concentrate the RBCs to hematocrit of about 75%. The RBCs are stored for up to 6 days at 1 – 6 °C before being frozen in a cryoprotectant (40% w/v glycerol) and stored in the frozen state at minus 65 °C or colder for up to 10 years. Once it is determined that they will be needed for transfusion, the frozen RBCs are thawed. They are then deglycerolized by sequential washing with hypertonic (12%) saline followed by normal (0.9%) saline mixed with 0.2% glucose. Following deglycerolization, they are re-suspended in AS-3 additive solution and stored at 1 – 6 °C, until ready for transfusion. DRBCs suspended in AS-3 are Food and Drug Administration (FDA)-approved for transfusion for up to 14 days when processed on the Haemonetics Automated Cell Processor ACP215, an FDA 510(k)-cleared, closed processing system device. DRBCs are licensed under the respective Service Blood Program licenses.

The first operational frozen blood bank was established in 1956 at Chelsea Naval Hospital (Boston), in part to determine the practicality of frozen blood usage aboard Navy ships. In 1966, under Department of Defense (DoD) direction, the Navy Bureau of Medicine and Surgery established the first frozen blood bank in a combat zone at Navy Station Hospital, DaNang, Republic of South Vietnam. Over a seven-month period, 465 DRBC units were transfused to severely injured casualties. In the 1980s, the DoD froze 68,000 RBC units. Those units were pre-positioned throughout several geographic Combatant Commands in direct support of current and future military medical contingency operations.

FDA-approved DRBCs are typically used at Role 2 and higher Medical Treatment Facilities (MTFs) but could be used in the pre-hospital setting after thawing and deglycerolization if appropriately transported. DRBC storage and processing are organic to certain naval vessels and Service depots in the Pacific Command (PACOM) Area of Responsibility. Army MTFs and Medical Detachment Blood Support units do not have the organic mission or capability to process and store frozen units of blood. Use of this capability is based on operational necessity outside of PACOM.

CLINICAL INDICATIONS FOR USE

Each unit of DRBCs:

- Should be considered equivalent to a fresh unit of RBCs since they are frozen within 6 days of collection and have a 14-day shelf-life upon deglycerolization.
- Contains more than 80% of the RBCs present in the original unit of blood.
- Provides the same physiologic benefits as liquid RBCs.
- Carries the same expectation for post-transfusion survival as liquid-stored RBCs.
- Contains significantly lower concentrations of proteins associated with non-hemolytic transfusion reactions.
- **The primary indication for use of frozen and deglycerolized RBCs is as a supplement to liquid RBCs during surge periods of increased transfusion requirements in order to decrease casualty hemorrhagic morbidity and mortality.**

  DRBCs may be used in lieu of liquid-stored RBCs for all RBC transfusion requirements including massive transfusions. The Joint Trauma System (JTS) Performance Improvement Branch analyzed data from the DoD Trauma Registry (DoDTR) and Massive Transfusion database and found no statistically significant

difference in outcomes or transfusion-related complications between patients who received at least 1 unit of DRBCs as part of their massive transfusion and those who received none (See Appendix A). A single center prospective randomized trial comparing DRBCs to liquid-stored RBCs in stable trauma patient's revealed decreased inflammatory marker and D-dimer levels and increased tissue oxygenation measured by near infrared spectroscopy in patients transfused DRBCs. There were no differences in clinical outcomes.

- Transfusion monitoring:
  - **Clinical:** Treat as a routine liquid-stored RBC transfusion before, during, and after transfusion, and for a suspected or actual adverse event.
  - **Laboratory:** Consider obtaining pre- and post-transfusion Hgb/Hct and Base Excess/Deficit or lactate levels.

DOCUMENTATION

Clinical documentation for a frozen and deglycerolized transfusion is the same as for a liquid transfusion. In addition:

1. The **physician** may order use of DRBCs (for example, when washed RBCs would be preferred to reduce risk of transfusion reaction to plasma proteins in some patients), but in practice, the MTF will use DRBCs and liquid-stored RBCs interchangeably based on inventories and logistical considerations.
2. The **laboratory** will establish and maintain a process to document DRBC transfusions in a manner that will facilitate future evaluation of recipients, including but not limited to:
   - Blood component identifiers.
   - Date of blood component receipt in frozen state.
   - Date of thaw/deglycerolization/additive process and resulting expiration date.
   - Casualty identifiers (including nationality and ABO/Rh categorization).
   - Date of transfusion.
   - Transfusion indication.
   - Transfusion reaction, nature, and outcome.

OPERATIONAL CONSIDERATIONS

Thawing and deglycerolization are time-consuming processes. Thawing a frozen RBC unit takes about 35 minutes in a plasma thawer and about 45 minutes in a 42°C water bath. The process of deglycerolization of one blood unit on an Automated Cell Processor (ACP)-215 takes approximately one hour, not including time for initial unit thawing and labeling/release of deglycerolized product. When using multiple ACP215s, maximal throughput from initial thawing to unit release/availability can average up to 1 U every 2-3 hours per device. However, problems with device performance, supply limitations, and technician training can lead to slower availability times. In periods of predictable operational requirements, it may be advisable to pre-thaw and deglycerolize several units so as not to incur the delay of preparation at the time they are needed.

PERFORMANCE IMPROVEMENT (PI) MONITORING

INTENT (EXPECTED OUTCOMES)

All patients who receive DRBC transfusions have accurate documentation in the medical record of the quantity of transfused blood and any transfusion-related adverse events.

PERFORMANCE/ADHERENCE MEASURES

In patients who were transfused DRBCs, there was accurate documentation in the medical record as to the quantity of blood transfused and any transfusion-related adverse events.

DATA SOURCE

- Patient Record
- DoDTR
- CENTCOM blood bank logs
- Theater Medical Data Store

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed biannually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the combined responsibility of the trauma team leader and blood bank officer to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

APPENDIX A: MASSIVE TRANSFUSION WITH DRBC COMPARED TO STANDARD MASSIVE TRANSFUSION

	p value	
Overall Mortality	0.241	63 cases/63 controls matched for age, ISS, total RBC within 24 hours, patient category, gender
Complications	**p value**	
Transfusion Reaction	N/A	No cases in sample
Coagulopathy	0.271	63 cases/63 controls matched for age, ISS, total RBC within 24 hours, patient category, gender, initial Base deficit, initial temperature, initial INR
Renal Failure	0.57	60 cases/60 controls matched for age, ISS, total RBC within 24 hours, patient category, gender, extremity injury
DVT	0.753	23 cases/23 controls matched for age, ISS, total RBC within 24 hours, patient category, gender, extremity injury
Respiratory Failure	N/A	No cases in sample

Sixty-three patients in Afghanistan were identified between Jan 10 - Sep 11 as having a massive transfusion which included deglycerolized blood (DRBC). A control population of 525 patients with non-DRBC massive transfusion from the same time period and theater was found in the JTTR to provide comparison of overall mortality.

CONCLUSION: With the data available, there appears to be no statistical difference in mortality outcome in theater for patients receiving deglycerolized blood (DRBC) as part of a massive transfusion when compared to patients receiving no DRBC as part of a massive transfusion. Additionally, there seems to be no significant difference between massive transfusions with DRBC and without DRBC in the development of complications for transfusion reaction, coagulopathy, renal failure, deep vein thrombosis (DVT), or respiratory failure.

Completed 23 March 2012

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

EXECUTIVE SUMMARY

Between 2001 and 2011, a total of 501 soldiers sustained lower genitourinary injuries (GU) trauma, with a total of 729 injuries. The injury patterns are varied, including penile (20%), testicular (36%), scrotal (39%), and urethral (5%). Genitourinary surgery constitutes approximately 1.15% of procedures performed for combat injuries. During forward deployment, surgeons usually deploy without urology support. The most common procedures mirror the above injury patterns: testis (20.6%), bladder (18.8%), scrotum (17.7%), and kidney (13.5%). The single most common individual procedures performed were unilateral orchiectomy (394, 9.9%), suture of laceration of scrotum and tunica vaginalis (373, 9.4%), nephroureterectomy (360, 9.1%), and other suprapubic cystostomy (268, 6.8%). All deploying surgeons may be required to evaluate, stage, and surgically manage genitourinary, and gynecologic conditions.[1,2] Surgery on the male genitalia, bladder, and kidney were the most commonly required genitourinary operative procedures in deployed facilities, and so all surgeons should be familiar with the appropriate treatment of these injuries.

These guidelines provide direction for the identification of life threatening GU injuries, control of hemorrhage, establishment of urinary drainage, and the preservation of function where possible.

BACKGROUND

Management of GU injuries requires a systematic approach to imaging and treatment that adheres to established surgical and trauma principals. Critical to initial evaluation is to establish the hemodynamic stability of the patient, as treatment algorithms differ depending on the clinical situation. Stable patients are afforded a rigorous radiographic evaluation that identifies genitourinary sites of hemorrhage and injury and allows for the safe establishment of urinary drainage. Recognizing that intra-abdominal GU injuries are often associated with significant vascular and visceral injuries, unstable patients benefit from rapid surgical evaluation and hemorrhage control [2]. Preservation of as much tissue as possible, particularly when dealing with the external genitalia, should be an additional goal for far forward surgical units. Current combat care principles allow for multiple surgical evaluations along the path of evacuation to tertiary centers outside the theater of operations where tissue re-evaluation, wound irrigation, further debridement, and definitive treatment can occur.[3]

EVALUATION AND TREATMENT

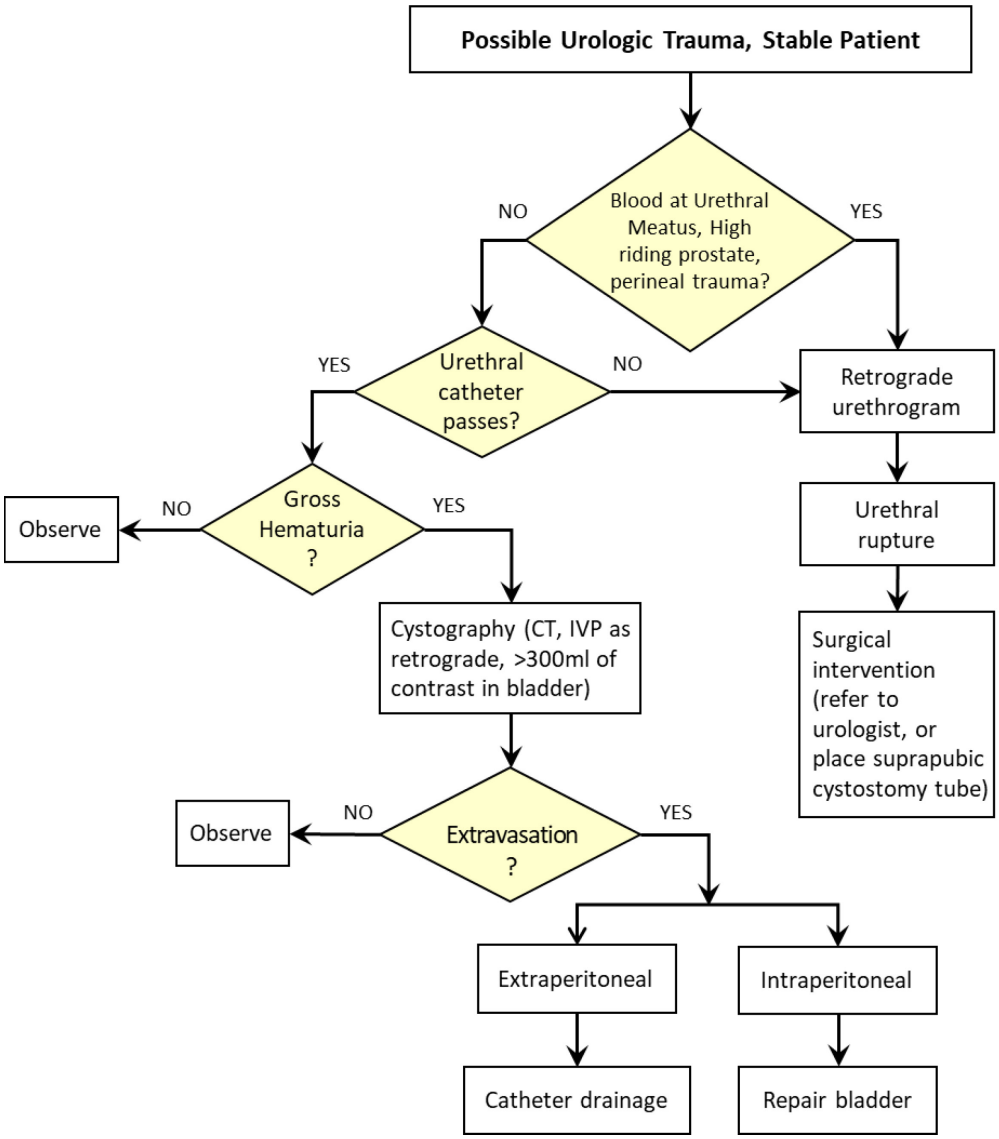
Ten percent of all combat casualties in current U.S. conflicts have GU injuries, which may be blunt, penetrating, or combined in nature. The extensive use of improvised explosive devices (IED) has resulted in a substantial number of penetrating injuries that include GU organs as part of a complex wounding pattern with trauma to the abdomen, pelvis, perineum, and extremities.[3,6-9] A significant reduction in kidney injuries has been noted in combat casualties wearing body armor.[10] Not surprisingly, given the mechanism of injury, the most commonly injured GU structures are the external genitalia and lower urinary tract (bladder and urethra).[6,11,12] A thorough trauma evaluation is therefore mandatory in all severely injured patients following proper Advanced Trauma Life Support (ATLS) based initial evaluation and management.

INITIAL EVALUATION

Severely injured patients typically warrant bladder drainage via catheter placement to facilitate urinary drainage and assist with hemodynamic monitoring via hourly assessment of urine output. Urethral injury should be suspected in the setting of scrotal hematoma, blood at the urethral meatus, or a high-riding prostate on initial rectal exam. In these situations, urethral integrity must be confirmed prior to catheter placement. Retrograde urethrography may also be necessary if there is any resistance to initial catheter placement (See Figure 1. Algorithm for Urologic Trauma below.) [4, 13] The inability to safely pass a catheter should prompt placement of a suprapubic catheter.

A urinalysis should be obtained after successful catheter placement and the presence of any gross hematuria should be immediately noted. Evaluation for renal injury is necessary in patients with gross hematuria or in patients with microscopic hematuria and an initial systolic BP < 90 mmHg (after they become hemodynamically stable); and in patients with mechanism of injury or physical examination findings suggestive of renal injury (i.e. rapid deceleration, rib fracture(s), flank ecchymosis, or a penetrating injury to the abdomen, flank, or lower chest).[13] The stability of the patient, operational environment and capabilities of the medical treatment facility will dictate which resources for radiographic and surgical evaluation are available at each echelon of care. The preferred imaging test to evaluate for renal and ureteral injury is an intravenous (IV) contrast enhanced computed tomography (CT) with delayed imaging.[13] If unavailable, "one shot" Intravenous Pyelography (IVP) can be performed. During the initial evaluation of patients with hematuria, it is important to note that the severity of hematuria (gross or microscopic) does not necessarily correlate to the severity of injury.[12] For example, it is possible to have minimal hematuria despite high grade renal injury such as disruption of the ureteropelvic junction, pedicle injuries, and segmental arterial thrombosis.[11] Conversely, low grade renal injury can result in ongoing gross hematuria. Thus, proper injury staging and high index of suspicion is critical regardless of hematuria severity. In cases of blunt renal trauma, most injuries can be managed conservatively. The grading scale is listed in Renal Injury in Appendix A: Urological Diagnosis and Treatments.)

Figure 1. Algorithm for Urologic Trauma



RENAL TRAUMA

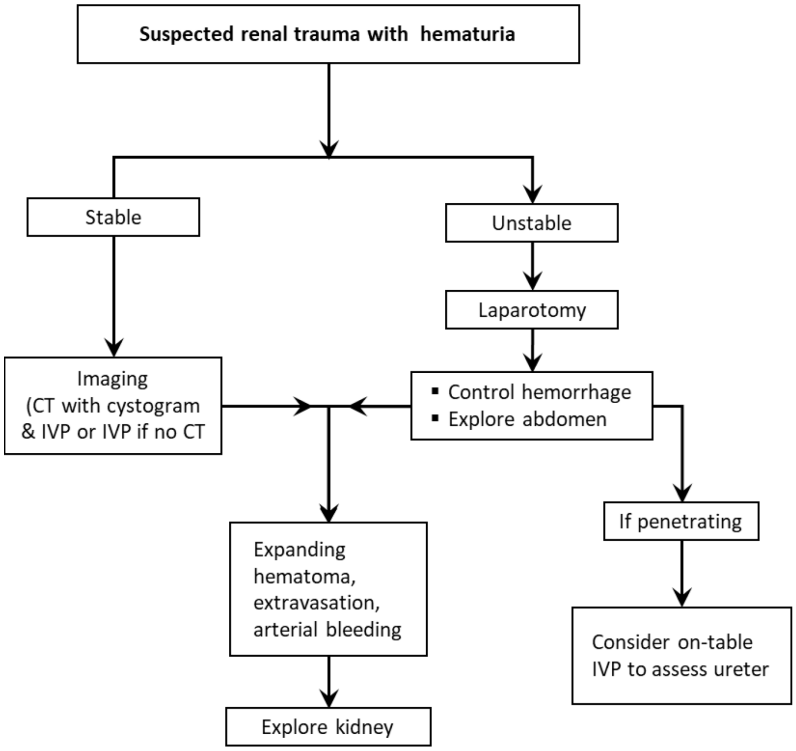
Patients with penetrating renal injuries often have associated injuries to other intra-abdominal organs that require laparotomy. Following principles of vascular injury in the retroperitoneum, all Zone 2 (perinephric) penetrating wounds should be explored. Generally, in the case of blunt injury a hematoma confined to the retroperitoneum can be left undisturbed; however persistent bleeding, expanding hematoma, or medial hematomas suggest a hilar, aortic, or caval injury and warrant direct evaluation.[4]

The decision as to repair or remove the damaged kidney at that time depends on the salvage-ability of the kidney and the ability of the patient to tolerate the procedure. Kidney preservation should be considered if possible. Nephrectomy may be required for the severely damaged kidney or the unstable patient. Verification of the presence of contralateral kidney by palpation or on-table imaging (IVP) should be determined prior to nephrectomy. High velocity kidney injuries are difficult to reconstruct and often result in nephrectomy. (See Nephrectomy in Appendix A: Urological Diagnosis and Treatments.) [14]

Ureteral injuries are nearly always secondary to penetrating trauma and a high index of suspicion based upon suspected bullet or fragment trajectory is necessary to avoid missing the diagnosis; IVP can be helpful if it can be performed in the operating room.[15,16] Hematuria may be absent and the only clue may be injuries to organs close to the path of the ureter or an unexplained rise in serum creatinine. If a ureteral injury is identified it may be repaired, but at a minimum should be 'tagged' for later repair and widely drained. Extracorporeal drainage ('stent to skin' or percutaneous nephrostomy- however, this is not widely available in theater)[15] is an option, with a small feeding tube or stent, if surrounding tissue destruction prevents early repair. (See Appendix A: Urological Diagnosis and Treatments.) [14]

An algorithmic approach to renal trauma management is presented in Figure 2 below.

Figure 2. Renal Trauma Algorithm



BLADDER TRAUMA

Bladder injuries may be secondary to blunt or penetrating trauma. Bladder rupture from blunt trauma is typically associated with pelvic fracture and results in gross hematuria. Thus, the combination of these two findings (hematuria + pelvic fracture) warrants retrograde plain film or CT cystography to evaluate for bladder injury.[13] Penetrating bladder injury must be excluded when the trajectory of the penetrating object is near the pelvis or lower abdomen.[18] Retrograde (plain film or CT) cystography should be performed prior to exploratory laparotomy if possible. However, when imaging is not possible prior to abdominal exploration, large intraperitoneal bladder injuries can be rapidly excluded by filling the bladder in a retrograde fashion with 200-300 ml of sterile saline or dilute methylene blue via the Foley catheter and inspecting for leakage of the fluid into the peritoneal cavity. Extraperitoneal injuries cannot be reliably excluded using this technique.

While intraperitoneal bladder rupture **must** be repaired, extraperitoneal rupture can be managed non operatively with Foley catheter drainage. Extraperitoneal injuries may benefit from immediate repair when pelvic fractures result in exposed bone spicules in the bladder lumen, concurrent rectal or vaginal lacerations may lead to fistula formation to the ruptured bladder, for bladder neck injuries that may not heal with catheter drainage alone, or when the patient is undergoing open repair of concurrent abdominal pelvic injuries in the stable patient.[13] Bladder repair is performed using a two layer closure with absorbable sutures and bladder catheter drainage. (See Bladder Injuries in Appendix A: Urological Diagnosis and Treatments.) It is important to note that bladder injury from penetrating trauma has a high incidence of concurrent rectal injury.[18]

URETHRAL TRAUMA

Urethral injuries are identified by retrograde urethrography. Blunt anterior urethral injuries should be stented with a urethral catheter when possible or diverted with a suprapubic cystostomy. Posterior urethral injuries, however, can be managed with suprapubic cystostomy alone.[13] A judicious attempt to realign the urethra endoscopically can be performed at subsequent operative evaluations when the patient is clinically stable several days following injury.[13] Penetrating anterior urethral injuries can be primarily repaired with fine absorbable suture over a urethral catheter when the degree of soft tissue injury/contamination is limited. However, when complex blast injury results in anterior urethral injury associated with significant soft tissue loss of the perineum and/or genitalia, urinary diversion alone (transurethral or suprapubic) is sufficient to facilitate urinary drainage until the patient can be evaluated by a urologist who can assist with the wound care and complex urethrogenital reconstruction frequently needed in these cases. This is most appropriately performed at a Role 4 or Role 5 facility following multidisciplinary planning.

EXTERNAL GENITALIA

With the rise in dismounted complex battle injuries from explosive devices in current combat operations and polytrauma involvement of the lower extremities, perineum, pelvis, and lower abdomen; greater attention has turned to the management of soft tissue injury to the external genitalia and urethra. Testicular injuries are easily missed due to small scrotal entry wounds in some cases and require a high index of suspicion when evaluating patients with significant blast injury. Bedside ultrasonography with vascular flow settings can easily identify testicular rupture and compromised vascular flow.[19] Initial operative management involves a thorough assessment of the injury sites with removal of wound contaminants and debridement of non-viable tissue. This is done in conjunction with copious, low-pressure irrigation of the wound.[5] (See External Genitalia Injuries in Appendix A: Urological Diagnosis and Treatments.)

In addition to arterial bleeding, vascular structures of the penis and scrotum should be addressed on initial surgery, specifically, the corpora cavernosa, corpus spongiosum, and bilateral testes. Lacerations to the corpora

cavernosa can be closed with absorbable suture taking care to avoid the dorsal neurovascular structures. Aggressive over sewing of the corpus spongiosum, however, should also be avoided in favor of site specific closure to its tunical covering reducing risk of ischemic changes distal to the injury site in these complex wounds.[19,20] Patients with penetrating scrotal wounds or evidence of testicular rupture on exam should undergo scrotal exploration. Ruptured testes are managed with irrigation and debridement of non-viable seminiferous tubules. The tunica albuginea is then closed and returned to the scrotum.[13] A tunica vaginalis flap can be used to close the defect when there is insufficient tunica to obtain a tension free closure over the exposed tubules. [21] A delay in managing a testicular injury is acceptable when the patient is too unstable or there is insufficient expertise to manage it at initial exploration. Every attempt should be made to salvage viable testicular tissue especially when both testicles are involved or a unilateral orchiectomy is required. The injured testis should be wrapped in saline soaked gauze and protected with multiple layers of additional dressing. A vacuum assisted dressing is NOT appropriate if the tunica is left open. All findings should be documented and communicated to the next echelon of care.

The superficial fascia and skin layers of the penis can and should be left open following high energy trauma. Loose approximation of these layers with interrupted suture allows continued tissue evaluation and additional wound debridement. A moist gauze or negative pressure dressing is appropriate. Alternatively, Penrose drains can be placed between loosely approximated interrupted sutures. In cases where scrotal closure is impossible, the testis can be covered with a non-adherent dressing followed by a negative pressure dressing. Creation of a sub dermal thigh pouch is rarely necessary during early surgical care.

With the recent introduction of female combatants to all roles in the military, GU injuries in female patients have risen. Of the nearly 1500 service members in Operation Enduring Freedom and Operation Iraqi Freedom between 2001 and 2013, 1.3% were female. Injuries described in female service members thus far include bladder injury, vulvar injury, vaginal injury, bladder and perineal injury. Currently there is limited evidence-based direction in the management of these injuries. Initial care should focus on good exposure of the injured tissue with a complete examination to include the vaginal vault, urethra, and meatus with low pressure irrigation and judicious debridement of devascularized tissue. Limited debridement should be practiced around the clitoris favoring repeat examinations in the operating room with intervention as needed. This new injury pattern is being prospectively tracked to best ensure appropriate care.[22,23]

AEROMEDICAL EVACUATION CONSIDERATIONS

As for all postoperative and litter bound patients, Deep Venous Thrombosis prophylaxis should be considered. See The Prevention of Deep Venous Thrombosis – Inferior Vena Cava Filter CPG, 02 Aug 2016 (ID: 36).

- Vibration and increased tissue edema in flight will increase pain. Ensure adequate en-route pain control by ordering breakthrough pain medications.
- Do not remove drains within the 12 hours prior to movement.
- Consider filling Foley Catheter balloon with water to reduce expansion in flight.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

- All patients with GU injury (kidney, ureter, bladder, testicles/ovaries, penis, external genitalia)
- All trauma patients with hematuria.

INTENT (EXPECTED OUTCOMES)

1. All patients in the population of interest have a documented GU exam.
2. Patients with renal trauma undergo attempted renal salvage unless hemodynamically unstable.
3. Patients with hematuria are evaluated for GU injury (imaging if stable, surgical exploration if unstable).
4. Patients with blunt trauma, pelvic fracture and hematuria are evaluated for bladder injury with cystography.
5. Patients with suspected urethral injury or blood at the meatus undergo retrograde urethrography.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest with documented GU exam.
2. Number and percentage of patients with renal trauma who are hemodynamically stable on admission to Role 2 or 3 who undergo nephrectomy at the same role of care.
3. Number and percentage of trauma patients with hematuria who are evaluated for GU injury (imaging if stable, surgical exploration if unstable).
4. Number and percentage of patients with blunt trauma, pelvic fracture and hematuria who are evaluated for bladder injury with cystography.
5. Number and percentage of patients with suspected urethral injury or blood at the meatus who undergo retrograde urethrography.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Division.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: UROLOGICAL DIAGNOSIS AND TREATMENTS

Diagnosis	Treatment
Hematuria	• Place Foley catheter during trauma assessment unless contra-indicated such as blood at the urethral meatus or other evidence of urethral injury (pelvic fracture). • Perform a retrograde urethrogram (RUG) before attempted catheterization when there is concern for a urethral injury. • RUG – Obtain an oblique plain film of the pelvis with the patient's bottom leg flexed at the knee and the top leg straight. Severely injured patients or those with suspected spine fractures can be left supine**.** Alternately, C-arm or fluoroscopy can be used. A 12Fr Foley catheter or catheter tipped syringe is inserted into the fossa navicularis, the penis placed on traction, and 20 mL of undiluted water soluble contrast injected under gentle pressure. Images are obtained. The study is considered normal only if contrast enters the bladder without extravasation. • For an anterior urethral injury, plan on repair in the operating room (OR). For a posterior urethral injury, a suprapubic catheter can be placed in the OR, or percutaneously in the emergency department (ED) for patients who do not need surgery and an appropriate kit is available. For partial urethral disruption by RUG, a single attempt with a well-lubricated catheter may be attempted by an experienced team member in the ED. • If the catheter passes, and gross hematuria is noted, proceed with GU diagnostic evaluation for bladder injury or a renal/ureteral source. CT scan with delayed images and CT cystogram are appropriate imaging studies (see technique description following).

Renal Injury	• Clinicians should perform diagnostic imaging with intravenous (IV) contrast enhanced computed tomography (CT) with delayed imaging in stable blunt trauma patients with gross hematuria or microscopic hematuria and systolic blood pressure < 90mmHG or in any stable trauma patients with mechanism of injury or physical exam findings concerning for renal injury (e.g., rapid deceleration, significant blow to flank, rib fracture, significant flank ecchymosis, penetrating injury of abdomen, flank, or lower chest).
	• **Renal Injury Grading**
	  • Grade 1: Sub-capsular hematoma
	  • Grade 2: Small parenchymal laceration
	  • Grade 3: Deeper parenchymal laceration without entry into collecting system
	  • Grade 4: Laceration into collecting system with extravasation; vascular injury with contained hemorrhage
	  • Grade 5: Shattered kidney or renal pedicle avulsion
	• Hemodynamically stable patients can be managed without surgical exploration in most cases.
	• Hemodynamically unstable patients with no or transient response to resuscitation should have immediate intervention.
	• Vascular repair is indicated for salvageable kidneys with renal artery or vein injury.
	• Ureteral stenting may be needed for enlarging urinoma or persistent urinary extravasation with fever, pain, ileus, fistula, or infection.

Renal Exploration During Abdominal Operation	• Stable perirenal hematomas found at time of exploration should not be routinely opened. • Penetrating injuries to retroperitoneal zone 2 should be explored. • Renal exploration should be performed at time of laparotomy for persistent bleeding, expanding hematoma, or a central hematoma suggesting a renal hilum injury
Nephrectomy	• Total nephrectomy is immediately indicated in extensive renal injuries when the patient's life would be threatened by attempted renal repair. • A common surgical approach is a lateral to medial mobilization of the kidney to expose the renal pedicle after incision of the peritoneal attachments of the colon to the lateral wall. While there is insufficient data to recommend initial vascular control of the renal pedicle through a mesentery window prior to exploration, this remains an acceptable principle for isolated renal surgery. • Damage control by packing the wound to control bleeding and attempting to correct metabolic and coagulation abnormalities, with a plan to return for corrective surgery within 24 hours is an option.

Diagnosis	Treatment
Renal Repair and Partial Nephrectomy Principles	• Non-surgical management can result in renal preservation even with high grade injuries. Renal repair is appropriate after gaining hemorrhage control and hemodynamic stability for potentially salvageable kidneys identified during exploration. • **Technique**: Complete renal exposure, debridement of nonviable tissue, hemostasis by individual suture ligation of bleeding vessels, watertight closure (absorbable suture), drainage of the collecting system, and coverage/approximation of the parenchymal defect. • Perform partial nephrectomy if reconstruction is not possible: the collecting system must be closed and the parenchyma covered with fat or omentum. Consider the use of hemostatic agents and tissue sealants if available. • Place ureteral stent for persistent urinary extravasation.
Ureteral Injuries	• Identification of ureteral injury requires a high index of suspicion. It should be evaluated with IV contrast enhanced CT with delayed imaging or direct inspection during laparotomy if preoperative imaging is not available. • Ureteral contusions can be managed by stenting or judicious excision of the injured area with primary anastomosis depending on its severity. Simple ureteral lacerations should be closed primarily. • Complete transections of the ureter proximal to the iliac vessels can be repaired using a tension free, end to end, spatulated anastomosis over a ureteral stent. Transections distal to the vessels should be managed with a ureteral reimplantation over a stent. A psoas hitch or Boari flap may be necessary in some cases. • In cases of inadequate ureteral length to re-anastomose or hemodynamic instability of the patient intraoperatively, a pediatric feeding tube or open ended ureteral catheter may be placed in the proximal ureter and brought out through the skin and placed to closed drainage. Reconstruction of the ureter can then be performed at a future date. • An ureteropelvic junction (UPJ) avulsion injury should undergo re-anastomosis of the ureter to the renal pelvis over a stent. • A drain should be considered after ureteral repair.
Bladder Injuries	• Perform retrograde cystography in patients with gross hematuria and a mechanism concerning for bladder injury, finding on exam or imaging concerning for bladder rupture, or pelvic ring fracture. • Retrograde cystography can be done by CT or plain film. For CT cystogram use diluted Conray to reduce scatter artifact from the contrast. A minimum of 300 ml is needed for an adequately study. Plain film images should include a scout film and an AP image with or without oblique views both with the bladder full and again after it is drained. • **Extraperitoneal** extravasation of contrast can be managed with Foley catheterization alone in most cases. Open repair is indicated for complicated ruptures that include pelvic fractures with exposed bone spicules in the bladder and concurrent rectal or vaginal lacerations that may lead to fistula formation. Patient's undergoing exploration for other indications that are appropriately stable and those with significant bladder neck involvement should be considered for closure. A transvesical approach can reduce disruption of the pelvic hematoma. • **Intraperitoneal** rupture requires open repair, two-layer closure with absorbable suture, and perivesical drain placement. A large caliber urethral catheter without suprapubic catheter is usually sufficient for bladder drainage. Patients with complex lower extremity, pelvic, or perineal injuries and those requiring prolonged immobilization may benefit from suprapubic catheter drainage as well. • Follow up cystography should be performed prior to catheter removal

Diagnosis	Treatment
Urethral Injuries	• **Diagnosis**: A RUG should be performed in any case of suspected urethral injury. For partial urethral tears, a single attempt at urethral catheterization with a well lubricated catheter may be attempted by an experienced provider. • **Anterior urethral injuries**: Primary repair of uncomplicated penetrating injury to the anterior urethra may be performed using fine absorbable sutures with careful mucosal to mucosal apposition over a urethral catheter. Immediate repair should not be performed in the setting of extensive tissue damage or urethral loss, patient instability, or surgeon inexperience. Bleeding from the corpus spongiosum can be controlled with site specific fine absorbable suture. Bladder drainage should be established by urethral catheterization or suprapubic drainage. • **Posterior urethral injuries**: These injuries are typically associated with pelvic fractures or deep penetrating trauma. Suprapubic urinary drainage with delayed reconstruction is the accepted treatment for the majority of cases. Endoscopic alignment may be attempted within the first several days after injury in a hemodynamically stable patient. Aggressive attempts at realignment should be avoided.
External Genitalia Injuries	• The primary goals in the management of genital injuries are hemorrhage control and tissue preservation. • Hemorrhage can occur from small arteries on the dorsal penile shaft and/or the spermatic cord. These vessels can be managed with precise cautery. • Large volume, low pressure, irrigation with normal saline should be performed with each surgical intervention. Delayed wound closure is appropriate for significant injuries with considerable tissue damage. Negative pressure wound dressings are well tolerated but often require creative placement techniques when applied to the genitalia. A non-adherent silicone or hydrophilic white foam dressing can be used to cover exposed testicles or freshly repaired corporal tissue when using a negative pressure dressing. • **Penile injury** may include the corpus spongiosum or corpus cavernosa, and can result in continued hemorrhage. These can be repaired by approximation of the tunical margins with absorbable sutures in a hemostatic fashion following irrigation and debridement of necrotic or devitalized tissue. • The glans is well vascularized and can generally be closed with interrupted absorbable suture. • **Scrotal injuries** are managed in a similar fashion as other soft tissue wounds. Small penetrating injuries can result in significant testicular damage. There should be a low threshold for surgical exploration in these cases. The scrotum should undergo irrigation and debridement with primary or delayed closure. Widely spaced absorbable suture and a Penrose drain can be used in lieu of a negative pressure dressing when delayed closure is required. • **Testicle injuries** can be diagnosed with physical exam or scrotal ultrasound. CT or sonography may also show evidence of foreign bodies or air in the scrotum or abnormality of one or both testes. Equivocal cases should be explored. Necrotic testicular tissue should be debrided and the capsule closed with absorbable suture. A tunical vaginalis flap can be used when the tunica albuginea is deficient for closure.

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Global Snake Envenomation Management (CPG ID: 81)

Guide providers in the evaluation and treatment of patients after snake bites.

Rapid Update (Jun 2023): removal of Promethazine recommendation in accordance with DHA Policy Memo 23-001 Discontinuation of Injectable Promethazine Usage at MTFs.

BACKGROUND

Snakebite, recently declared a neglected tropical disease and global health priority by the World Health Organization (WHO), results in an estimated 2.5 million envenomations, 138,000 deaths and over 500,000 cases of permanent disability worldwide every year.[1–10] Snake, spider, and scorpion envenomations are a common environmental and occupational hazard for military forces worldwide.[11–46] The consequences of an envenomation range from mild local effects to permanent disability or death, and the outcome is largely determined by the time to antivenom treatment and the level of training of the medical providers involved.

Once an envenomation has occurred, the provider and patient are racing against the clock to neutralize active venom components before extensive damage has occurred. Necrosis caused by cytotoxic venoms cannot be reversed, but it can be prevented by early antivenom administration or arrested before further damage can occur in cases of late antivenom treatment.[1,7,47,48] Hemotoxic venoms can induce coagulopathies within an hour of the envenomation which is quickly followed by a standard progression of worsening local and systemic external and internal bleeding. Neurotoxic venoms can act rapidly and be fatal. Africa is one of the few places in the world with snakes like the black mamba that are capable of killing a human within one hour due to direct effects of the venom, and most patients with mamba envenomation who are not rapidly treated with antivenom will die within 2 - 6 hours from respiratory arrest.[1,49] When a neurotoxic bite occurs, rapid antivenom administration prior to the onset of respiratory muscle weakness can arrest the progression of descending paralysis before serious systemic manifestations develop.[1,50,51] Every hour wasted between bite and antivenom administration is strongly associated with sharp increases in mortality and the development of chronic or permanent sequelae including amputation, disfigurement, PTSD, blindness, kidney injury, infections, and partial or complete loss of function of the bitten limb.[4,7,8,52–58]

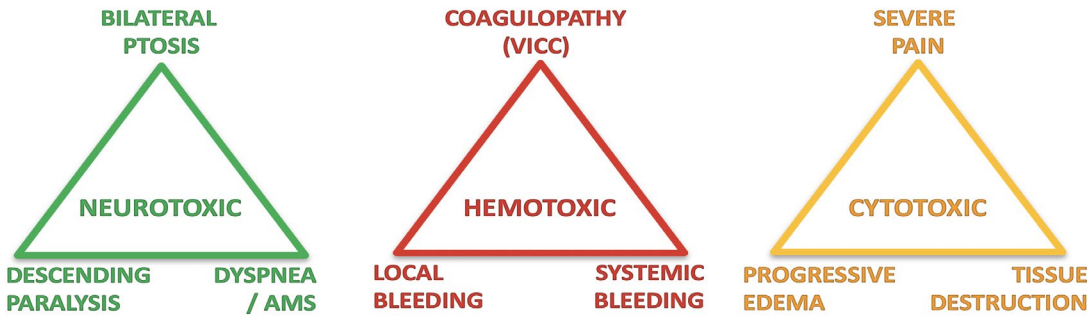
This CPG will cover the continuum of snakebite care for snake envenomations in all combatant commands.

GENERAL PRINCIPLES OF SNAKEBITE MANAGEMENT

Don't try to ID the snake. Snake identification is unreliable and should not be purposely attempted. DO NOT attempt to catch or kill the snake; treatment is clinical and the snake species does not need to be identified.

There are 3 major clinical syndromes of snakebite envenomation worldwide and 3 major signs and symptoms of each. All dangerous snakes capable of injuring or killing a human will produce at least one sign or symptom from at least one of the 3 major snakebite syndromes (neurotoxic, hemotoxic, and cytotoxic). Specific antivenoms required will vary regionally but the major triads are applicable globally.

Figure 1. Snakebite Clinical Triads



CLINICAL PEARLS ON SNAKEBITES AND ANTIVENOM TREATMENT

1. **Not all snakes are venomous and not all snake bites result in snake envenomations!**

   Most snake species pose no danger to humans, and only ~600 of the >3500 snake species worldwide are considered potentially dangerous to people. However, dangerous species are often drawn to human habitations in search of food, water, or shelter and envenomations are very common in the developing world.

2. **Roughly 25% of bites from dangerously venomous snakes are harmless "dry bites" where no venom is injected!**

   a. This means that even if you know that the snake which bit your patient is a dangerous species, it does not mean that they will require antivenom treatment. While the exact percentage varies by species, on average 25% of bites from venomous snakes are considered "dry bites" that are designed to scare away a potential threat that is too big to eat without wasting venom. Venom is metabolically expensive to produce and snakes will try to conserve their venom for potential prey items whenever possible.

   b. The dry bite phenomenon explains why many people believe that useless or potentially harmful interventions such as venom extractors or black stones are effective: these patients appear to have recovered miraculously thanks to the treatment they applied but in reality, they were never sick to begin with!

3. **Snakebite treatment should always be determined by the clinical presentation and evolution of signs and symptoms in the patient rather than the identity of the snake that bit them!**

   a. Remember that many snakebites are likely to have resulted from harmless snakes and that roughly 1/4 people bitten by a truly dangerous species are likely to be fine because of the dry bite phenomenon. Many dangerous species have harmless mimics and vice versa. Do not attempt to identify snake species if you are not a herpetologist. **Identifying the snake species will not change your patient care!**

   b. Do not treat patients simply based on the fact that they were bitten by a dangerous snake species.

   c. Always treat snakebite patients based on the signs and symptoms they develop. A patient who hands you a dead mamba and develops no signs or symptoms of envenomation does not require antivenom unless they develop progressive signs and symptoms of an envenomation. Conversely, a patient who has no recollection of a snakebite or believes that the species responsible was harmless will require treatment for an envenomation if they subsequently develop progressive swelling, systemic bleeding, or other signs of the three major snake envenomation triads.

4. **There are no absolute contraindications to antivenom for patients with symptomatic snake envenomations. The high risk of permanent damage posed by untreated venom in the body is far greater than the low risk of anaphylaxis associated with high-quality modern antivenoms.**

   a. Antivenom administration at the earliest possible opportunity is the gold standard of snakebite care and most effective way to reduce the risk of death or permanent disability in these patients.

   b. Early antivenom administration in the field at or near the point of injury may resolve the underlying envenomation before any serious systemic signs or symptoms develop.

   c. Ignore the packaging and manufacturer insert and treat according to the guidelines outlined in this CPG.

d. Dosing and administration of recommended antivenoms in this CPG can vary significantly between products; refer to the specific instructions included later in this CPG for whichever product you have on hand.

e. Antivenom may be given by IV or IO injection or infusion.[54,59] An IV is preferable but IO is an acceptable alternative and should not influence the efficacy of the medication.

f. DO NOT give antivenom by IM or SQ injection, even if packaging says you can. The serum concentrations of antivenom given by IM or SQ injection will never achieve more than a fraction of the serum concentrations rapidly achieved from the intravascular route.

g. DO NOT administer test doses of antivenom to check for hypersensitivity prior to giving the full dose. Test doses have no predictive value for identifying patients with hypersensitivity and waste both time and antivenom.[60–63]

h. **Antivenom dosage is not weight-based** and there is no difference in dosing between adults and children.

i. **The dose of antivenom needed is proportional to the dose of venom injected into the patient**. The quantity of venom injected into the patient corresponds to the severity of the envenomation syndrome(s).

j. Additional antivenom should be given as many times as needed until control of envenomation is achieved.

k. Overdosing antivenom is not a concern during the active treatment phase, and the worst-case scenario is an allergic reaction. If a patient develops a reaction to large doses, it will most likely manifest as a late reaction called serum sickness (fever, rash, arthralgia, etc.) 1 - 3 weeks later and can be managed with antihistamines or steroids if the patient is uncomfortable. Serum sickness may be uncomfortable but is not life-threatening.

5. **Establish a timeline and trend changes over time. Serial assessments and documentation are essential because the resolution of certain clinical findings will be used to determine when the right dose of antivenom has been given. At a minimum always document the following:**

   a. Time and date when bite occurred

   b. Time elapsed from bite to presentation under your care (record as minutes, hours, days, etc.)

   c. Time when the first dose of antivenom is given (defined as Hour 0, written as H0)

   d. Always repeat a complete snakebite assessment at hours 2, 4, 6, 12, and 24 (H2, H4, H6, H12, H24) since the first dose of antivenom was given in order to trend the clinical evolution of the syndrome over time.

6. **Snakebites are clinically dynamic emergencies and can change dramatically until control has been achieved.**

   Patients may present with one syndrome initially and develop signs and symptoms of another later on (for example, a patient who presents with local pain and mild swelling at H0 could develop local bleeding or ptosis at H4). Always look for signs and symptoms of all three triads when reassessing and redirect your treatments if needed according to the clinical evolution observed in your patient.

UNIVERSAL APPROACH TO THE SNAKEBITE PATIENT

INITIAL PRIORITIES

1. Airway, breathing, circulation, and rapid antivenom administration are the critical priorities during stabilization and treatment of a snakebite casualty.

    a. Assess ABCs; identify and address any immediate life threats before proceeding.

    b. Refer to the Sudden Collapse Syndrome Treatment Protocol for specific instructions on stabilization and management of patients who develop rapid onset shock ± angioedema, altered mental status, systemic bleeding, and/or diarrhea within the first 30 minutes after a snakebite

    c. Treat emergent secondary issues that may be present (such as anaphylaxis or hypovolemic shock) according to standard clinical protocols.

    d. Establish IV or IO access in a non-bitten limb before proceeding.

2. ***DO NOT apply constricting bandages or tourniquets*** as these may worsen local tissue injury and increase the risk of permanent disability.[64–66]

    If a tourniquet is already in place, do not remove it until you are ready to treat and resuscitate the patient as a rapid decompensation can occur.[67,68] When removing a tourniquet do so sequentially (loosen for several seconds - tighten - observe - repeat) over 20 - 30 mins; if symptoms develop at any time administer antivenom and wait at least 30 minutes before resuming tourniquet release. Ideally, this should not be done until antivenom is available but prolonged evacuation times without antivenom may necessitate the risk of earlier removal to prevent limb death. Refer to the Joint Trauma System Tactical Combat Casualty Care (TCCC) Guidelines for tourniquet conversion in these settings.

3. If and when conditions allow, minimize patient activity, and loosely immobilize bitten limb to reduce movement without constricting tissues.

    a. If antivenom is not available onsite, choose whichever evacuation option will safely get your patient to the antivenom in the shortest amount of time. This includes allowing the patient to walk to help when needed.

    b. If conditions allow during transport, maintain the bitten limb in a position of comfort that is elevated above the level of the heart.

    c. Once the patient has arrived at the clinic and can be placed in a bed, aggressively elevate the bitten limb (aim for a minimum 60º angle in a supine patient if possible and tolerated by patient) to reduce oncotic pressure on swollen tissues.

4. Evaluate for specific signs and symptoms of snake envenomation. See Table 1 and refer to specific criteria for initial antivenom treatment and repeat doses for additional information.

FOCUSED ASSESSMENT AND EXAMINATION

Perform a physical examination and history focused on identifying signs and symptoms of neurotoxic, hemotoxic, and cytotoxic envenomation syndromes.

1. Determine how long ago the bite occurred. Circle the site of the bite wound and write the specific time that it occurred with a permanent marker on the patient
2. Do not rely on fang marks to assess the possibility of a bite or envenomation. Snakebites can leave punctures, multiple lacerations, or even no obvious fang marks whatsoever.
3. Rapid examination for signs of **pain, swelling, or tissue destruction (cytotoxic syndrome).**
   Separately mark the leading edge of both pain (dashed line) and edema (solid line) with a permanent marker and record time of observation next to each line
4. Rapid examination for signs of **local or systemic bleeding (hemotoxic syndrome)**
   a. Inspect the bitten limb for persistent local bleeding > 30 mins from the bite wound (if visible) or other lesions.[1,70–72]
   b. Inspect the molar gingiva and other mucosa for signs of systemic bleeding.[1,69,70]
5. Rapid examination for signs of **neuromuscular weakness (neurotoxic syndrome)**
   a. Evaluate respiratory muscle weakness by single breath count testing[72] and repeat periodically to trend improvement or deterioration in respiratory function over time.
      - The single breath count (SBC) test requires no equipment to perform and is easily performed in austere settings:

        Ask the patient to take a deep breath and count as high as possible in their normal speaking voice without taking another breath. Demonstrate the test to the patient, then have them repeat it and record the highest number reached.
        - SBC correlates closely with spirometry.
        - Normal SBC is approximately 50 and SBC < 20 is associated with the need for mechanical ventilation.
      - If spirometry is available, this can be used in place of the single breath count test by evaluating the negative inspiratory force (NIF) and/or forced vital capacity (FVC).
        Conduct gross assessment and pay particular attention to the following:
        - Signs and symptoms of descending flaccid paralysis: Ptosis, diplopia, neck flexor muscle weakness, bulbar weakness, etc.[1,54,73]
        - Signs and symptoms of parasympathetic / cholinergic crisis: SLUDGE mnemonic - Salivation, Lacrimation, Urination, Defecation, GI distress, Emesis
   b. Perform and/or check the clinical laboratory tests listed below (if available).

UNSTABLE PATIENTS

Sudden Collapse Syndrome Treatment Protocol

Patient presents within 30 minutes of the bite with rapid onset shock ± angioedema, altered mental status, systemic bleeding, and diarrhea.[1]

1. Stabilize with IM or IV epinephrine and fluids as per anaphylaxis protocols
2. Intubate for airway edema not rapidly responsive to epinephrine
3. Follow epinephrine immediately with a high dose of the appropriate regional antivenom given by rapid IV or IO push during the resuscitation
4. Maintain blood pressure with IV or IO fluids and epinephrine until antivenom has taken effect to reverse the hypotension.

See Sudden Collapse Syndrome section for more information.

LAB TESTS

Advanced laboratory tests include:

- Complete Blood Count (CBC)
- Hemoglobin (Hb) or Hematocrit (HCT) if no CBC but separate testing for either Hb or HCT is available
- Prothrombin Time (PT), Partial Thromboplastin Time (PTT), and International Normalized Ratio (INR)
- Fibrinogen
- Comprehensive Metabolic Panel (CMP)
- Creatine Kinase (CK)

Simple coagulation test for austere environments: Use the Whole Blood Clotting Test (WBCT) as described in Appendix A to diagnose and monitor coagulopathy if advanced labs not available

TRANSPORT FACTORS

1. If the patient is being medically evacuated from the field or between roles of care, confirm that the receiving facility has an adequate supply of the appropriate regionally specific antivenoms listed in this CPG to ensure treatment coverage against local species of concern.

   NOTE: *Evacuation is not an alternative to antivenom administration. A patient whose snakebite warrants evacuation will require antivenom. The earlier it is given the greater the chance of full recovery without permanent disability. DO NOT delay administration of antivenom in the field to a patient with an envenomation.*

2. If clinical evidence of envenomation is present and treatment is occurring in a hospital setting, always admit to a bed with continuous vital sign monitoring if available. If no initial clinical evidence of envenomation, admit for 24 hours for observation. If treating in the field, continuously monitor patient trends for signs of progression, improvement, or deterioration.
3. Symptoms should be expected within 24 hours; if the patient is completely asymptomatic after 24 hours then they most likely received a dry bite and can be discharged. See Discharge Criteria.

INITIAL ANTIVENOM TREATMENT

Antivenom dosing, preparation, and administration recommendations vary by product. Coverage, initial dosing, preparation, and administration of antivenoms are included in this CPG. Refer to guidelines for the specific product prior to administering the antivenom.

Table 1. Simplified universal diagnosis and treatment criteria for snakebite worldwide

	Neurotoxic Syndrome	Hemotoxic Syndrome	Cytotoxic Syndrome
Mild	Local S/Sx (paresthesias; neuropathic pain; piloerection; muscle spasm, fasciculations)	Coagulopathy ± persistence of local bleeding from bite wound > 30 mins after bite	Severe pain; edema below elbow or knee; limited blistering within several inches of the bite wound
Moderate	Systemic S/Sx (bilateral ptosis GI symptoms; visual, auditory, or other sensory disturbances; widespread hyperesthesia)	Moderate systemic bleeding (old scabs, gingival bleeding, epistaxis, etc.); bruising distant from the bite wound	Edema above elbow or knee but not beyond shoulder or hip; moderate local blistering along bitten limb segment
Severe	Difficulty speaking; altered mental status; respiratory muscle weakness causing difficulty breathing; shock or otherwise unstable patient	Active GI bleed (usually hematemesis) or other internal bleeding; severe anemia; altered mental status; shock or otherwise unstable patient	Progressive edema beyond shoulder or hip; severe necrosis or widespread blistering; symptomatic bite to head, neck, or torso; altered mental status; shock or otherwise unstable patient
Criteria for additional AV doses at hours 2, 4, 6, 12, 24 (as needed)	*Additional doses if:* *persistence or worsening of systemic neurotoxic S/Sx. Continue to re-administer 2 vial boluses as needed at hours 2, 4, 6, 12, and 24 until indications of improvement begin to appear* (↑SBC, ↑LOC, ↑strength, etc.)	*Additional doses if:* *persistence, resumption, or new onset of any active external or internal bleeding* ***OR*** *S/Sx of active venom confirmed by secondary recurrence of abnormal WBCT*	*Additional doses if:* *significant increase in edema (such as beyond major joint)* ***OR*** *significant increase in pain (severity of pain and/or how far pain radiates up the bitten limb)*

S/Sx = Signs & Symptoms; SBC = Single Breath Count Test; LOC = Level of Consciousness; WBCT = Whole Blood Clotting Test

Table 2. All Combatant Commands – First Line Antivenoms

First Line Antivenoms for All Combatant Commands		
AFRICOM 1st Line Antivenoms	**First Line Antivenoms with Regional Coverage against All Three Major Syndromes (Neurotoxic/Hemotoxic/Cytotoxic)** **Sub-Saharan Africa:** Broad-spectrum coverage for all neurotoxic/hemotoxic/cytotoxic snakebite syndromes by known or unknown species - *POLYSERP-P: Initial dose = 6 vials / Additional doses = 2 vials as needed* **North Africa:** Broad-spectrum coverage for all neurotoxic/hemotoxic/cytotoxic snakebite syndromes by known or unknown species - *POLYSERP-M: Initial dose = 6 vials / Additional doses = 2 vials as needed*	
AFRICOM Abbreviations	**POLYSERP-P** = POLYSERP PAN-AFRICA **POLYSERP-M** = POLYSERP MENA	
CENTCOM 1st Line Antivenoms	**First Line Antivenoms with Regional Coverage against All Three Major Syndromes (Neurotoxic/Hemotoxic/Cytotoxic)** **CENTCOM**: Broad-spectrum coverage for all neurotoxic/hemotoxic/cytotoxic snakebite syndromes by known* or unknown species - *POLYSERP-M: Initial dose = 6 vials regardless of severity / Additional doses = 2 vials as needed* **CENTRAL ASIA**: *If patient has a confirmed *Gloydius halys* bite (rare!), use SIOBP-G as 1st line if available. If unavailable or unconfirmed ID give POLYSERP-M - SIOBP-G: *Initial dose = 2 vials / Additional doses = 2 vials as needed*	
CENTCOM Abbreviations	**POLYSERP-M** = POLYSERP MENA **SIOPB-G** = *Gloydius halys* monovalent	
EUCOM 1st Line Antivenoms	**First Line Antivenoms with Regional Coverage Against All Three Major Syndromes (Neurotoxic/Hemotoxic/Cytotoxic)** **UK or Scandinavia**: Broad-spectrum coverage all neurotoxic/hemotoxic/cytotoxic syndromes from European *Vipera* species - *VIPERATAB (1st line): Initial dose = 2 vials (one box), additional doses = 1 – 2 vials as needed* - *VIPERFAV (2nd line): Initial dose = 1 – 2 vials, additional doses = 1 vial as needed* **Outside UK/Scandinavia**: Broad-spectrum coverage all neurotoxic/hemotoxic/cytotoxic syndromes from European *Vipera* species - *VIPERFAV (1st line): Initial dose = 1 – 2 vials, additional doses = 1 vial as needed* - *VIPERATAB (2nd line): Initial dose = 2 vials (one box), additional doses = 1 – 2 vials as needed*	
EUCOM Abbreviations	**VIPERFAV** = VIPERFAV **VIPERATAB** = ViperaTAb	
INDOPACOM 1st Line Antivenoms	**First Line Antivenoms with Regional Coverage Against Neurotoxic Syndrome** **Southeast Asia**: Broad-spectrum for all neurotoxic - *TRC-NPAV: Initial dose 10 vials* *Additional doses = 5 vials as needed* - TRC-*NPAV* is the 1st line for all neurotoxic bites in SE Asia outside of the circumstances listed below: **Marine environments**: Sea snake envenomations - *CSL-SS: Initial dose = 3 vials* *Additional doses = 1 vial as needed* **Maluku/West Papua islands**: Neurotoxic - *CSL-P: Initial dose = 3 vials* *Additional doses = 1 vial as needed*	**First Line Antivenoms with Regional Coverage against Hemotoxic and/or Cytotoxic Syndromes** **Southeast Asia**: Broad-spectrum for all hemotoxic/cytotoxic (1st line in SE Asia) - *TRC-HPAV: Initial dose = 10 vials, additional doses = 2 vials as needed.* TRC-HPAV is the 1st line for all hemotoxic/cytotoxic bites in SE Asia outside of circumstances listed below: **Korean Peninsula/Eastern China**: Viper envenomations (Cytotoxic +/- Hemotoxic) Korean Mamushi species (*Gloydius brevicaudus, G. ussuriensis, G. intermedius*) - KOVAX-AKA*: Initial dose = 1 - 2 vials, additional doses = 1 vial as needed* **Taiwan / Se China / N Vietnam / Laos:** Sharp-nosed viper (*Deinagkistrodon acutus*) - NIPB-SNV*: Initial dose = 2 vials, additional doses = 1 vial as needed* **Japan**: Viper envenomations (Cytotoxic +/- Hemotoxic) If Japanese HABU (*Protobothrops spp.)* envenomation: - CSTRI-HABU*: Initial dose = 1 -2 vials, additional doses = 1 vial as needed* If Japanese Mamushi (*Gloydius blomhoffi*) envenomation:

First Line Antivenoms for All Combatant Commands		
	Eastern China/Taiwan: Neurotoxic - *NIPM-NBB: Initial dose = 5 vials* *Additional doses = 5 vials as needed*	- CSTRI-MAMU*: Initial dose = 1 -2 vials, additional doses = 1 vial as needed* **Japan/China/ N & S Korea/Vietnam/E Russia**: Rhabdophis spp. - Hemotoxic without Cytotoxic Spontaneous bleeding develops within several days of bite without cytotoxicity. - *JSI-AYA: Initial dose = 1 -2 vials, additional doses = 1 vial as needed*
INDOPACOM Abbreviations	**TRC-NPAV** = Neuro Polyvalent Antivenom **CSL-P** = CSL Polyvalent **CSL-SS** = CSL Sea Snake **NIPM-NBB** = Naja atra - Bungarus multicinctus Bivalent	**TRC-HPAV** = Hemato Polyvalent Antivenom **KOVAX-AKA** = Agkistrodon Mamushi Antivenom **JSI-AYA** = Anti-Yamakagashi Antivenom **CSTRI-HABU** = Kaketsuken Habu Antivenom **CSTRI-MAMU** = Kaketsuken Mamushi Antivenom **NIPM-SNV** = Sharp-nosed Viper Monovalent
NORTHCOM 1st Line Antivenoms	**First Line Antivenoms with Regional Coverage Against Neurotoxic Syndrome** **United States**: Coral snake envenomations *- Initial 3-5 vials NACSA, additional doses not needed if 5 vial initial dose given* **United States/Canada**: Pit viper envenomations* *- CROFAB: Initial dose = 4-6 vials, Additional doses = 4-6 vial as needed* *- ANAVIP (rattlesnakes only): Initial dose = 10 vials, Additional doses = 10 vials as needed* *Follow unified treatment algorithm (Lavonas 2011)	**First Line Antivenoms with Regional Coverage against Hemotoxic and/or Cytotoxic Syndromes** **United States/Canada**: Broad spectrum coverage all hemotoxic/cytotoxic syndromes* Any pit viper envenomation (rattlesnake, copperhead, cottonmouth): - *CROFAB: Initial dose = 4-6 vials, additional doses = 4-6 vials as needed* Rattlesnake envenomations only: - *ANAVIP: Initial dose = 10 vials, additional doses = 10 vials as needed* NOTE: Anavip is only indicated by FDA for rattlesnake envenomations; not for copperheads or cottonmouths at this time; however, it is likely effective against all North American pit vipers. Follow *Unified treatment algorithm for the management of crotaline snakebite in the United States* (Lavonas et al. 2011) for specific dosing and management guidelines on pit viper bites.

1. The presence of one or more of the criteria for each category in Table 1 (universal treatment) is generally sufficient to diagnose the syndrome, determine severity, and initiate treatment. Patients who present with "mixed syndromes" (signs and symptoms of > 1 syndrome present) receive the same initial doses of antivenom as those presenting with a single syndrome.

   To identify the appropriate antivenom and initial dosing for your patient, refer to the regionally specific snakebite treatment for each combatant command section later in this document. Each COCOM section includes instructions on preparation, dosing, and administration of each antivenom.

2. In certain instances, pretreatment with a low dose of SQ epinephrine prior to antivenom administration may be recommended to reduce the risk of an adverse reaction to antivenom therapy. Refer to pretreatment with epinephrine to prevent early adverse reactions for specific guidelines on pretreatment.

3. The majority of severe early reactions to antivenom occur within the first 5 - 60 minutes after antivenom administration. ***Observe and monitor the patient closely at the bedside for a minimum of one hour after each dose of antivenom has been given***.

   Refer to management of mild, moderate, and severe antivenom reactions for specific guidelines on how to manage mild, moderate, or severe reactions to antivenom therapy

ADJUNCT TREATMENTS & SUPPORTIVE CARE

SUPPORTIVE CARE & ONGOING MANAGEMENT

Provide supportive care and address secondary issues related to the envenomation as follows:

1. Anticipate the need for aggressive airway management with intubation and prolonged ventilation in all patients presenting with neurotoxic envenomation, particularly those who present late with impending respiratory failure or fail to respond to antivenom.

   - For any neurotoxic snakebite producing a cholinergic crisis, consider atropine 0.5 mg IV/IO titrated by auscultation to dry up bronchial and oral hypersecretions posing a risk to airway or breathing.

     Repeat original dose every 5 minutes until resolution of crackles, rales, bronchospasm has been achieved. Pediatric atropine doses should be weight based at a dose of 0.01 mg/kg, up to 0.25 mg.

   - For neurotoxic snakebites in the Middle East, North Africa, and Central Asia without cholinergic crisis, but causing ptosis and respiratory muscle weakness, consider administering trial dose of 0.5 mg atropine followed by 1.0 mg neostigmine IV/IO to temporarily reverse neuromuscular weakness and delay the need for intubation. Pediatric doses should be weight based at a dose of 0.01 mg/kg, up to a maximum of 0.25 mg atropine with 0.5 mg neostigmine.[54,74–77]

     Not all patients will respond, but those who do will show temporary improvement (reversal of ptosis, increased respiratory muscle strength, etc). If no response to neostigmine, do not reattempt. If positive response is achieved, repeat every 1 - 4 hours as needed (maximum dose in 24 hours = 10 mg adults / 5 mg pediatric) until antivenom has definitively reversed the paralysis.

2. For hemotoxic envenomations, all internal and external active bleeding should cease within 30 – 60 minutes of antivenom administration once the appropriate dose has been given. Packed red blood cell or whole blood transfusion can be considered if the patient is in hemorrhagic shock.[17,69,70, 78-82] Platelets, fresh frozen plasma, cryoprecipitate, TXA, and ***other agents are not effective in these cases*** due to the mechanism of the venoms.

3. Ketamine and fentanyl are preferable for analgesia. Histamine release from morphine may mask signs of an allergic reaction or worsen hypotension.
4. It is important to keep the limb significantly elevated (> 60º is ideal) whenever possible to limit dependent edema and swelling.
5. DO NOT routinely de-roof or aspirate blisters, bullae, or blebs unless they are causing significant discomfort or uncontrolled rupture appears imminent. If abscess is suspected, treat according to existing protocols for abscess management.
6. DO NOT perform fasciotomy for snakebites. Compartment syndrome is rare in snakebites. Even in cases of confirmed elevated intracompartmental pressure, patients who received antivenom without fasciotomy experienced better outcomes (shorter recovery time and less long term morbidity) than those who received fasciotomy.[83–86] Appropriate use of antivenom should resolve the underlying issue that is producing the elevated intracompartmental pressures.
7. DO NOT routinely administer antibiotics unless signs and symptoms of an infection are present. Direct infections are rare from most snakebites when prompt, appropriate treatment is given.[54]

ONGOING MONITORING & NEED FOR ADDITIONAL ANTIVENOM

1. Monitor the patient closely for signs of progression in the initial hours of treatment until control of symptoms has been achieved.

   Serial assessments for signs and symptoms of the neurotoxic, hemotoxic, and cytotoxic syndromes should be repeated at hours 2, 4, 6, 12, 24 (H2, H4, H6, H12, H24).

2. Within the first 24 hours, antivenom may be given at hours 0, 2, 4, 6, 12, and 24 according to the specific criteria for antivenom treatment listed under Criteria for Initial Antivenom Treatment and Repeat Doses.
   a. If the treatment criteria have not been resolved at any of these intervals, give an additional dose of antivenom at hours 2, 4, 6, 12, and 24 until control is achieved. Refer to specific dosage instructions for each product listed by COCOM.
   b. If symptoms reappear or persist for more than 24 hours after the first dose of antivenom was given, additional treatment intervals should be discussed with a physician expert.
   c. If 10 or more vials of a single antivenom have been given without any indications of improvement, consider changing to 2nd line antivenom if possible as species may not be covered. If any indications of improvement have been observed, continue with the antivenom you are using.
3. If the patient is asymptomatic but coagulopathy persists 24 hours after the first dose of antivenom was given, administer a dose of antivenom and repeat laboratory tests every 24 hours until resolution.
4. Continuous monitoring for effectiveness of antivenom dose must be done. Occasionally, pockets of venom can be trapped in swollen tissue compartments and escape into the bloodstream once circulation has improved. This is called recurrent envenomation and is most common within the first 24 - 48 hours after a severe bite with extensive swelling and blistering.[78,87–93]
   a. Continuous clinical monitoring includes hourly checks of vital signs, urine output, and detailed assessment for new or worsening signs of neurotoxic, hemotoxic, or cytotoxic envenomation.
   b. Serial laboratory studies including CBC, CMP, PT/PTT/INR, CK, fibrinogen levels (or WBCT if no advanced testing available) may be repeated every 2 hours while signs of envenomation persist.
   c. After signs of clinical resolution, monitoring can decrease to every 6 hours.

5. If indications of recurrent envenomation are detected more than 24 hours after the first dose of antivenom was given, treat as follows:
    a. Asymptomatic patient with coagulopathy and no other findings:
    Administer a dose of antivenom and repeat laboratory tests every 24 hours until resolution.
    b. Symptomatic patient with new or worsening pain, swelling, bleeding, neurotoxicity, or other indications of active envenomation:
    Administer an additional dose of antivenom every 2 hours until acute symptoms have resolved completely.

Discharge Recommendations

1. Patients should be held for at least 24 hours after resolution of all signs and symptoms, and the following steps should be completed prior to discharge:
    a. Repeat blood tests before releasing the patient to ensure resolution of coagulopathy.
    b. Administer a booster dose of tetanus toxoid if needed.
    c. Patients should be instructed to return if any new or worrying signs or symptoms develop.
2. Serum sickness is characterized by flu-like symptoms ± rash that typically develops between 1 - 3 weeks after antivenom administration. It is rare with highly purified modern antivenoms but may occur more frequently with some of the second and third line antivenoms listed in this CPG.[94–97]

    Serum sickness may be uncomfortable but is not dangerous. Management is either symptomatic or with a course of oral steroids.[94,95,97–99]

Criteria for Initial Antivenom Treatment & Repeat Doses

Cytotoxicity

The presence of significant local pain OR progressive edema OR signs of tissue destruction (bruising, blistering, necrosis) is an indication for initial administration of antivenom.[1,47,48,79,100–105] If any of these criteria (or other systemic signs and symptoms) are present, treat immediately and do not wait for irreversible damage to occur before deciding to give antivenom. Note that the progression of edema at any treatment interval is an indication to administer additional antivenom; however, edema may not begin to noticeably decrease for several days and severe edema may take 1 - 2 weeks or longer to completely resolve. WORSENING edema is therefore a treatment criteria, persistence of edema without any progression IS NOT a treatment criteria. Worsening pain that increases significantly in severity or moves proximally up the limb is another indicator for antivenom treatment.

Neurotoxicity

The onset, persistence, or resumption of systemic neurotoxic signs of envenomation (dyspnea, neck flexor muscle weakness, bulbar muscle weakness, reduced level of consciousness, ↓ respiratory muscle function, etc.) at any of the antivenom treatment intervals is always an indication to administer or re-administer antivenom.[1,50,107–109] Monitor respiratory function using negative inspiratory force (NIF) or forced vital capacity (FVC), single breath count test (SBC), capnography, spirometry, peak flow meters, etc.[1,54,72] In patients who have not reached the late stages of respiratory distress/arrest, the first indications that paralysis is improving may be apparent within 30 - 60 minutes once the right dose of antivenom has been achieved. In patients who are

already intubated, it may take hours for reversal to occur after antivenom. This typically occurs within 1 - 3 hours, but may take 6 - 12 hours or longer in some patients. There are numerous documented cases of patients who did not receive antivenom and required prolonged mechanical ventilation ranging from several days up to 13 weeks before recovery. Antivenom typically either reverses the syndrome before it progresses or dramatically shortens the duration of paralysis.

BLEEDING

The onset, persistence, or resumption of any active local or systemic bleeding at any of the standard assessment intervals (0, 2, 4, 6, 12, 24 hours) is always an indication to administer or re-administer antivenom regardless of the WBCT result at the time.[1,70,78,106,109–111] All external and internal bleeding will cease when the appropriate dose of antivenom has been given and actively circulating venom has been neutralized.

WBCT/COAGULATION TESTS

Tests of coagulation usually normalize within 2 - 6 hours after the effective dose of antivenom has been achieved but in some cases it may take longer for these labs to fully normalize after antivenom therapy.[78,112–120] WBCT procedure and interpretation is covered in Appendix A: Whole Blood Clotting Test (WBCT) for Venom-Induced Consumptive Coagulopathies (VICC).

There are three situations where an abnormal WBCT or other abnormal laboratory tests of coagulation (e.g. fibrinogen, PT/PTT/INR, etc) should be treated with antivenom:

1. Initial assessment at H0: Coagulopathy after a snakebite is an indication to give antivenom. If the coagulation test is abnormal but the patient is otherwise asymptomatic, repeat the test using a new glass tube to confirm the result prior to antivenom administration.[78,111,113,114,121]
2. H2, H4, H6, H12, H24: a previously normal coagulation test that changes to abnormal in the presence of any new symptoms meets criteria to administer an additional dose of antivenom. This also applies to a WBCT that was abnormal, normalized several hours after antivenom, but then changes to abnormal again later (recurrent envenomation).[78]
3. Coagulopathy remains abnormal at H24: If WBCT or other tests of coagulation remain abnormal at H24, administer an additional dose of antivenom and repeat every 24 hours until resolution of coagulopathy has occurred.

SUDDEN COLLAPSE SYNDROME

In rare cases, a patient may rapidly deteriorate in the first 5 - 30 minutes after the bite and present with profound hypotension, tachycardia, angioedema, altered level of consciousness, etc.[1,122–130] These patients should be aggressively treated for severe anaphylaxis and severe envenomation simultaneously. Treat anaphylaxis aggressively according to anaphylaxis protocols. Treat the envenomation with an initial high dose (at least 6 vials) of antivenom by rapid IV push, and support the patient with airway management, fluids, and other interventions as appropriate.[122,123,125,131,132] Most patients presenting with hypotension or angioedema are responsive to epinephrine, but may require IV epinephrine infusions to achieve this effect if they are unresponsive to IM epinephrine.[122]

How to Prevent Early Adverse Reactions to Antivenom

Epinephrine is the only prophylactic treatment (pretreatment) that has been shown to effectively reduce the incidence of early adverse reactions (EARs) such as anaphylaxis.[60,98,133–136]

1. ***DO NOT pretreat with steroids or antihistamines.***
2. ***DO NOT administer test doses of antivenom to check for hypersensitivity.***[60–63]

Relative contraindications to epinephrine pretreatment include age > 70, hypertension, ischemic heart disease, history of stroke, suspected or confirmed intracranial hemorrhage. No absolute contraindications.

1. Pretreatment with epinephrine prior to antivenom administration is not indicated by default for all antivenoms, and is recommended only under the following circumstances:
    a. Unstable snakebite patients with signs of shock.
    b. Known history of atopy (asthma, eczema, etc.), equine hypersensitivity, or severe reactions to antivenom in the past.
    c. Use of certain second or third line antivenom due to the high rate of serious EARs associated with these products.
2. Standard epinephrine pretreatment protocol:
    a. Adult dose is 0.25 mg of 1:1000 epinephrine given by SQ injection several minutes prior to antivenom administration.
    b. Pediatric doses should be weight based at a dose of 0.01 mg/kg, up to 0.25 mg.[60,134,135,137,138]
    c. Patients with signs of shock should be given epinephrine by IM injection in the lateral thigh

How to Manage Mild, Moderate & Severe Antivenom Reactions

Mild or Moderate Reaction during Infusion

1. Stop the infusion and manage mild or moderate reactions (e.g. nausea, vomiting, urticaria, pruritus, chills, fever, etc.) symptomatically as needed with antiemetics, antihistamines, steroids, etc.
2. Reassess the patient once the reaction has been controlled; if the antivenom treatment criteria for cytotoxic, hemotoxic, or neurotoxic syndromes have not resolved completely then resume the infusion at a slower rate over 30 minutes.
3. If giving via push, dilute the remaining dose of antivenom in a 100 - 500 mL bag of normal saline and give as 30-minute infusion.

Severe Reaction (Anaphylaxis) during Infusion

1. Stop the infusion and treat according to the anaphylaxis treatment protocol.
   Reassess the patient once the reaction has been controlled; if the antivenom treatment criteria for cytotoxic, hemotoxic, or neurotoxic syndromes have not resolved completely then resume the infusion at a slower rate over 30 minutes.

2. If giving via push, dilute the remaining dose of antivenom in a 100-250 mL bag of normal saline and give as 30-minute infusion.
3. If the reaction occurs, stop the infusion, and consult a physician expert via telemedicine to discuss next steps for management.

Anaphylaxis Treatment Protocol

NOTE: Intubate for airway edema not rapidly responsive to epinephrine.

If anaphylaxis occurs after antivenom administration, treat according to the following protocol:

1. First line treatment of anaphylaxis is rapid administration of 1:1000 epinephrine (initial adult dose = 0.5 mg IM in the lateral thigh for rapid absorption). Epinephrine can be repeated as needed until the patient has stabilized and/or an intravenous or intraosseous infusion administered as per standard protocols if the patient fails to respond to IM doses.
   Epinephrine should always be given prior to antihistamines or steroids to counter the immediate life-threats of bronchospasm and vasodilation.
2. After epinephrine has been given:
   a. Give methylprednisolone 125 mg IV
   b. Give diphenhydramine 50 mg IV.
   c. Consider adding an H2 antihistamine such as ranitidine.

If anaphylaxis occurs during administration of antivenom, stop the antivenom administration to treat the reaction, then resume the antivenom administration as described below. [15,61,95,99,128,129,140–146]

Late Reactions to Antivenom (Serum Sickness)

1. Serum sickness is characterized by flu-like symptoms ± rash that typically develops between 1 - 3 weeks after antivenom administration. Serum sickness may be uncomfortable, but it is not dangerous.
2. Serum sickness may be uncomfortable, but it is not dangerous.
3. Management is either symptomatic with antihistamines, acetaminophen, or with a course of oral steroids for patients who are in significant discomfort.[94,95,97–99]

Special Situations

If Antivenom is Unavailable

1. Antivenom is the gold standard of care for symptomatic snake envenomations. Early treatment is the best strategy to prevent death, amputation, or other serious disability. Management of snake envenomations when antivenom is not available should be directed at getting the patient to the antivenom (or vice versa) as quickly as possible to prevent irreversible damage to organs and tissues.
2. Mission planning before deployment should include research and procurement of the appropriate regionally specific antivenom(s) recommended in this CPG for your area of operation. If currently deployed without antivenom, efforts to acquire the appropriate antivenom(s) recommended in this CPG for your area of operations should be initiated through proper channels as fake or low-quality antivenoms are frequently found in local pharmacies throughout Africa and elsewhere in the developing world.

3. For specific management until antivenom can be obtained, follow the checklist and skip the steps related to antivenom administration until it has been obtained.

   Refer to Supportive Care measures for specific recommendations.

Military Working Dogs/Multipurpose Canines

All antivenoms can be administered to military working dogs (MWD) and multipurpose canines according to the treatment criteria and initial doses listed in this CPG; other management should be based on the MWD CPG.

Late Presentations and Treatment Delays

There is no defined time limit to antivenom therapy for a symptomatic snakebite. Early antivenom within the first minutes or hours after a bite is the best means of preventing morbidity or mortality, but antivenom remains effective at resolving reversible issues like coagulopathy and preventing further irreversible tissue damage even in patients who present many hours or days after the snakebite.[56,69,78,146,147]

Outdated Interventions That Should Not Be Performed

1. DO NOT cut, suck, electrocute, burn, or use chemicals on the envenomation site.
2. **DO NOT apply constricting bandages, tourniquets, or other circulation-reducing intervention!**
3. DO NOT use venom extractors or other commercial snakebite first aid kits. [148–152]
4. DO NOT administer test doses of antivenom to check for hypersensitivity as these are ineffective and waste both time and antivenom.[60–63]
5. DO NOT administer antihistamines or steroids as prophylactic pretreatment for prevention of anaphylaxis or other early adverse reactions (EARs) to antivenom as neither is effective as a premedication.[133,134]

OCULAR ENVENOMATION BY SPITTING COBRAS (VENOM OPTHALMIA)

Spitting cobras have modified fangs that allow them to spray venom into the eyes of a predator or perceived threat.[153–155] The venom spray widens like buckshot as it travels and the snakes aim at the glint of sunlight reflecting off of the target's eyes. The venom is harmless unless it enters the eyes (causing instantaneous burning, lacrimation, blurred vision, etc.) or the bloodstream by injection (such as a bite), through open wounds on the skin or inside of the mouth, or by ingestion (such as drinking a glass of venom with an ulcer). If a significant amount of venom enters the bloodstream through an open wound and produces typical symptoms of a snakebite, it is treated with antivenom like any other envenomation. For ocular exposure alone without signs of systemic envenomation, antivenom is not indicated and the management is like any ocular chemical exposure with copious irrigation. Spitting cobras can also deliver a venomous bite, so it is important to rule out an actual snakebite in patients who have encountered one of these snakes.

Signs and Symptoms

Immediate signs and symptoms of venom ophthalmia include intense local pain, swelling and/or spasms of the eyelid, lacrimation, and leukorrhea.[156] The primary concern is corneal epithelial injury which can lead to blindness by secondary infection or scarring if not treated correctly.[7,25,54,156–158] Treatment of venom ophthalmia is relatively simple and similar to managing a patient who has been splashed in the eyes with a harmful chemical solution.

First Aid

Confirm that the patient did not experience a snakebite in addition to the ophthalmia. Immediately irrigate the eye with copious quantities of water, normal saline, or a bland fluid such as milk if nothing else is available. Remove clothing and decontaminate the patient from head to toe with soap and water to prevent second re-exposure to dried venom.[54]

Clinical Management

Apply topical anesthetic eye drops (tetracaine) to facilitate thorough irrigation and examination of the affected eyes. Irrigate the eyes thoroughly using water or normal saline for ≥ 15 minutes.[156]

Fluorescein stain and examination using a slit lamp or ophthalmoscope for corneal injury. If present, treat with antimicrobial eye drops (such as tetracycline and chloramphenicol) or ointments and mydriatics. Reassess daily with slit lamp examination. If absent, consider benefits vs risks of antimicrobial eye drops.

Additional Treatments to Consider

Topical eye drops containing either epinephrine (1:1000) or phenylephrine (10%) are reported to immediately relieve the burning sensation produced by the venom.[54,156]

Contraindicated Treatments

Antivenom (topical or systemic) is not indicated for patients with ocular exposure to snake venom.[54,156,159] Topical steroids are contraindicated for these patients.

REGIONALLY SPECIFIC SNAKEBITE TREATMENT

There are a number of different antivenoms included in this CPG for snakebite treatment in AFRICOM, CENTCOM, INDOPACOM, EUCOM, NORTHCOM, and SOUTHCOM. The coverage, initial dosing, preparation, and administration vary between products and details for each of them are included. Simplified algorithms for selecting and dosing each antivenom are also included in each regional section below.

Whenever possible, broad-spectrum, field-stable antivenoms are recommended to enable syndromic diagnosis and treatment at the point of injury without the need to identify the species responsible for the bite. Citations of the relevant literature on safety, efficacy, and dosing for each product are provided in the references section.

Determine the appropriate first line antivenom for your area of operations prior to deployment using this section, then refer back to the Universal Approach to Snakebite Assessment, Diagnosis, and Treatment earlier in the document for detailed instructions and a stepwise approach to snakebite management throughout the course of care. Abbreviated antivenom guidelines for each regional combatant command are included below.

Categorization of Medically Significant Snake Species

The World Health Organization (WHO) classifies the risk posed by various venomous snakes by designating each species as either Category 1 or Category 2 as described below. WHO guidelines state that the “species listed in Category 1 within a country, territory or area should be considered as being of highest priority for antivenom production on the basis that available knowledge implicates them as being responsible for the greater burden in that particular setting.” [160]

WHO Category 1: Venomous Snakes of Highest Medical Importance

Defined as "highly venomous snakes which are common or widespread and cause numerous snakebites, resulting in high levels of morbidity, disability or mortality."

WHO Category 2: Venomous Snakes of Secondary Medical Importance

Defined as "highly venomous snakes capable of causing morbidity, disability or death, for which exact epidemiological or clinical data may be lacking; and/or which are less frequently implicated (due to their activity cycles, behavior, habitat preferences or occurrence in areas remote to large human populations)."

NOTE: Antivenom Infusion versus Direct Push:
For most first line antivenoms in this CPG, administration using either a) 100, 250, or 500 mL IV bag of isotonic fluids with 10-minute IV/IO infusion or b) direct IV push is recommended in order to get a full dose of antivenom onboard as quickly as possible and neutralize venom before further damage has occurred. However, if this is not possible it is acceptable to dilute antivenom in any size bag of isotonic solution you have available and give over 10 – 30 minutes.

CONTACT

For emergency consultations, call the ADVISOR telemedicine hotline (866-972-9966) and select toxicology from the phone menu.

For additional information about snake bite management or this CPG, email jordan@snakebitefoundation.org or call 415-218-2211.

AFRICOM

TREATMENT GUIDELINES

Safe and effective broad-spectrum, field-stable antivenoms are available for all three syndromes of snake envenomation in this AOR and treatment does not require identification of the species responsible. Snakebite treatment at the point of injury is recommended for AFRICOM due to prolonged evacuation times, high incidence of snakebites, and the high risk of death or permanent disability from many venomous snakes in the AOR if early antivenom treatment is not available.

ADVERSE REACTION MANAGEMENT

- If a mild or moderate reaction occurs, slow the infusion and treat symptomatically with antihistamines, steroids, and/or antiemetics as needed. Refer to management of adverse reactions for specific instructions.
- If a severe reaction such as anaphylaxis occurs, stop the infusion and treat according to the anaphylaxis protocol listed elsewhere in the CPG. Reassess the patient once the reaction has been controlled and resume the infusion at a slower rate if any of the specific criteria for antivenom treatment listed elsewhere in the CPG have not completely resolved.

Sudden Collapse Syndrome Treatment Protocol

Patient presents within 30 minutes of the bite with rapid onset shock ± angioedema, altered mental status, systemic bleeding, and diarrhea.[1]

1. Stabilize with IM or IV epinephrine and fluids as per anaphylaxis protocols.
2. Intubate for airway edema not rapidly responsive to epinephrine.
3. Follow epinephrine immediately with a high dose of the appropriate regional antivenom given by rapid IV or IO push during the resuscitation.
4. Maintain blood pressure with IV or IO fluids and epinephrine until antivenom takes effect to reverse hypotension.

See Sudden Collapse Syndrome section for more information.

CONTACT

For emergency consultations, call the ADVISOR telemedicine hotline (866-972-9966) and select toxicology from the phone menu.

For additional information about snake bite management or this CPG, email jordan@snakebitefoundation.org or call 415-218-2211.

Table 3. AFRICOM: First Line Antivenoms

	Neurotoxic Syndrome	Hemotoxic Syndrome	Cytotoxic Syndrome
Mild	Local S/Sx (paresthesias; neuropathic pain; piloerection; muscle spasm, fasciculations)	Coagulopathy ± persistence of local bleeding from bite wound > 30 mins after bite	Severe pain; edema below elbow or knee; limited blistering within several inches of the bite wound
Moderate	Systemic S/Sx (bilateral ptosis GI symptoms; visual, auditory, or other sensory disturbances; widespread hyperesthesia)	Moderate systemic bleeding (old scabs, gingival bleeding, epistaxis, etc.); bruising distant from the bite wound	Edema above elbow or knee but not beyond shoulder or hip; moderate local blistering along bitten limb segment
Severe	Difficulty speaking; altered mental status; respiratory muscle weakness causing difficulty breathing; shock or otherwise unstable patient	Active GI bleed (usually hematemesis) or other internal bleeding; severe anemia; altered mental status; shock or otherwise unstable patient	Progressive edema beyond shoulder or hip; severe necrosis or widespread blistering; symptomatic bite to head, neck, or torso; altered mental status; shock or otherwise unstable patient
Criteria for additional AV doses at hours 2, 4, 6, 12, 24 (as needed)	Additional doses if: persistence or worsening of systemic neurotoxic S/Sx. Continue to re-administer 2 vial boluses as needed at hours 2, 4, 6, 12, and 24 until signs of improvement begin to appear (↑SBC, ↑LOC, ↑strength, etc.)	Additional doses if: persistence, resumption, or new onset of any active external or internal bleeding **OR** S/Sx of active venom confirmed by secondary recurrence of abnormal WBCT	Additional doses if: significant increase in edema (such as beyond major joint) **OR** significant increase in pain (severity of pain and/or how far pain radiates up the bitten limb)

FIRST LINE (AFRICOM - SUB-SAHARAN): POLYSERP-P

POLYSERP/Inosan, Spain - POLYSERP PAN-AFRICA Polyvalent (POLYSERP-P)
(Freeze dried/Unrefrigerated) [1,106,161–164]:

1. Field-stable. Broad-spectrum coverage for 24+ species Cyto/Hemo/Neuro.
2. Single-source treatment option for all neurotoxic, hemotoxic, and cytotoxic snake envenomations in sub-Saharan Africa when the causative species is either unknown or among the 24 snakes for which this product is directly indicated. Only polyvalent to include boomslangs and only antivenom for mole viper envenomations. Directly or indirectly covers all of the WHO category 1 and category 2 snakes in this region for which an antivenom currently exists.
3. Initial dose = 6 vials all syndromes, additional doses = 2 vials as needed.

THIRD LINE (AFRICOM - NORTH AFRICA): POLYSERP-P

POLYSERP/Inosan, Spain - POLYSERP PAN-AFRICA Polyvalent (POLYSERP-P)
(Freeze dried/Unrefrigerated) [1,106,161–164]:

Indicated for all neurotoxic, hemotoxic, or cytotoxic envenomations in North Africa with no signs of improvement after 10 vials of POLYSERP-M and/or NAVPC-P. Directly or indirectly covers some of the WHO category 1 and category 2 snakes in North Africa.

Feasibility of use in austere environments: Recommended for use in operational settings and specifically designed to fill the capability gap for ground medics operating in these areas. Updated version of Inoserp Pan-Africa made specifically for the austere and operational medicine environment. Freeze-dried, unrefrigerated, stable at temperatures >100º F for at least 180 days without loss of efficacy. Broad coverage and simple dosing enable administration in the field for any symptomatic snakebite by unknown species in this region. Special operations and conventional units deploying to austere operational environments and areas with critical threat venomous species should carry 8 vials per medic. It is recommended that a reserve quantity is stocked in all role 2 and role 3 facilities in AFRICOM in case additional antivenom is needed upon arrival, and also to restock field medics that have used their supply.

Adverse reactions: High efficacy against all major syndromes and very low 0.2% incidence of serious adverse reactions based on current publications.

Indications: Broad spectrum polyvalent directly indicated for the treatment of neurotoxic, hemotoxic, and cytotoxic envenomation syndromes caused by 24 different species of African snakes from the families Elapidae, Viperidae, Colubridae, and Atractaspididae.

- NEUROTOXIC: *Dendroaspis angusticeps, D. jamesoni, D. polylepis, D. viridis; Naja anchieta, N. annulifera, N. haje, N. senegalensis; Naja melanoleuca*
- CYTOTOXIC and/or HEMOTOXIC: *Atractaspis irregularis; Bitis arietans, B. gabonica, B. nasicornis, B. rhinoceros; Cerastes cerastes; Dispholidus typus; Echis leucogaster, E. ocellatus, E. pyramidum; Naja katiensis, N. mossambica, N. nigricollis, N. nubiae, N. pallida*

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 6 vials
- HEMOTOXIC initial dose = 6 vials

- CYTOTOXIC initial dose = 6 vials

Additional dosing: Additional doses of 2 vials POLYSERP-P may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Reconstitute every 2 vials of POLYSERP-P in the same 10 mL syringe by mixing the first vial, drawing it back up into syringe, and injecting it into the second vial to yield 2 vials/1 syringe (6 vial dose = 3 syringes total). Administer sequentially via slow, continuous direct IV or IO push over approximately 2 minutes each. If a reaction occurs stop the push, treat the reaction, reassess response to treatment criteria. Dilute remaining dose in a 100 mL bag of isotonic fluids and administer via slow IV or IO infusion over 30 mins if needed.

Direct push is recommended for convenience, but POLYSERP-P may also be administered via IV or IO infusion. Mix in a 50 mL or 100 mL bag of isotonic fluids and administer the entire bag over 5 – 10 mins.

FIRST LINE (AFRICOM - NORTH AFRICA): POLYSERP-M

POLYSERP/Inosan, Spain - POLYSERP MENA Polyvalent (POLYSERP-M) (Freeze dried/unrefrigerated) [156–172]:

1. Field-stable. Broad-spectrum coverage for 27+ species Cyto/Hemo/Neuro.
2. Single-source treatment option for all neurotoxic, hemotoxic, and cytotoxic snake envenomations in North Africa (Algeria, Egypt, Libya, Morocco, Tunisia, Western Sahara) when the causative species is either unknown or among the 27 snakes for which this product is directly indicated. Directly or indirectly covers all of the WHO category 1 and category 2 snakes in this region for which an antivenom currently exists.
3. Initial dose = 6 vials all syndromes, additional doses = 2 vials as needed.

Feasibility of use in austere environments: Recommended for use in operational settings and specifically designed to fill the capability gap for ground medics operating in these areas. Updated version of Inoserp MENA made specifically for the austere and operational medicine environment. Freeze-dried, unrefrigerated, stable at temperatures >100º F for at least 180 days without loss of efficacy. Broad coverage and simple dosing enable administration in the field for any symptomatic snakebite by unknown species in this region. Special operations and conventional units deploying to austere operational environments and areas with critical threat venomous species should carry 8 vials per medic. It is recommended that a reserve quantity is stocked in all role 2 and role 3 facilities in AFRICOM in case additional antivenom is needed upon arrival, and also to restock field medics that have used their supply.

Adverse reactions: High efficacy against all major syndromes and low incidence of serious adverse reactions of approximately 1% based on current publications.

Indications: Broad spectrum polyvalent directly indicated for the treatment of neurotoxic, hemotoxic, and cytotoxic envenomation syndromes caused by 27 different species of Middle Eastern, North African, and Central Asian snakes from the families *Elapidae* and *Viperidae*. First line for snake envenomations in this region when the causative species is unknown or among those for which the product is directly indicated.

- **NEUROTOXIC**: Naja haje, N. oxiana; Walterinnesia aegyptia
- **CYTOTOXIC** and/or **HEMOTOXIC**: *Bitis arietans; Cerastes cerastes, C. vipera, C. gasperettii; Daboia palestinae, D. mauritanica, D. deserti; Echis. carinatus sochureki, E. coloratus, E. khosatskii, E. leucogaster, E. megalocephalus, E. omanensis, E. pyramidum; Macrovipera lebetina obtusa, M. l. transmediterranea, M. l. turanica; Montivipera bornmuelleri, M. raddei kurdistanica; Naja nubiae, N. pallida; Pseudocerastes persicus persicus, P. fieldi; Vipera latastei*

Pretreatment: ***Not routinely indicated*** unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 6 vials
- HEMOTOXIC initial dose = 6 vials
- CYTOTOXIC initial dose = 6 vials

Additional dosing: Additional doses of 2 vials POLYSERP-M may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Reconstitute every 2 vials of POLYSERP-M in the same 10 mL syringe by mixing the first vial, drawing it back up into syringe, and injecting it into the second vial to yield 2 vials/1 syringe (6 vial dose = 3 syringes total). Administer sequentially via slow, continuous direct IV or IO push over approximately 2 minutes each. If a reaction occurs stop the push, treat the reaction, reassess response to treatment criteria. Dilute remaining dose in a 100 mL bag of isotonic fluids and administer via slow IV or IO infusion over 30 mins if needed.

Direct push is recommended for convenience, but POLYSERP-M may also be administered via IV or IO infusion. Mix in a 50 mL or 100 mL bag of isotonic fluids and administer the entire bag over 5 – 10 mins.

SECOND LINE (AFRICOM - SUB-SAHARAN AFRICA): SAIMR-P

South African Vaccine Producers, South Africa - SAVP SAIMR Polyvalent Snake Antivenom (SAIMR-P) (Liquid/refrigerated) [50,173–181] :

1. Not field stable. Broad-spectrum against 10+ species neurotoxic and cytotoxic only.
2. Unknown neurotoxic and/or cytotoxic envenomation in sub-Saharan Africa or with no indications of improvement after 10 vials of POLYSERP-P. Will not treat hemotoxic envenomations. Southern Africa: Directly or indirectly covers all WHO category 1 and category 2 species for which an antivenom currently exists. East/Central/West Africa: Covers many cytotoxic and neurotoxic snakes in West, Central, and East Africa but has major coverage gaps with no efficacy against all WHO category 1 or category 2 hemotoxic snake species.
3. Initial dose = 10 vials neurotoxic/cytotoxic only, additional doses = 5 vials

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration. Recommend storing small quantities at strategically located Role 2 & 3 facilities in AFRICOM AOR.

Adverse reactions: High efficacy but very high rates of anaphylaxis ranging from 25% - 75% have been documented in multiple publications.

Indications: This polyvalent can be used to treat neurotoxic and cytotoxic envenomations by 10 different species of African snakes. The product has been used successfully to treat additional species of African snakes through paraspecific neutralization, but research in this area is limited and most experiences are anecdotal. The 10 species listed below are the official treatment indications recommended by the manufacturer:

- NEUROTOXIC SNAKES: *Dendroaspis polylepis, D. angusticeps, D. jamesoni, Naja melanoleuca, N. nivea, N. annulifera*
- CYTOTOXIC SNAKES: *Bitis arietans, B. gabonica, Naja mossambica, Hemachatus haemachatus*

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 10 vials
- Not indicated for hemotoxic

- CYTOTOXIC initial dose = 10 vials

Additional dosing: Additional doses of 5 vials SAIMR-P may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: Recommended for this antivenom. Administer 0.25 mg epinephrine injected SQ prior to beginning antivenom infusion to reduce the risk of a serious reaction. Pediatric epinephrine dose is weight based (0.01 mg/kg).

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

SECOND LINE, Boomslang (AFRICOM - SUB-SAHARAN AFRICA): SAIMR-B

South African Vaccine Producers, South Africa - SAVP SAIMR Boomslang Monovalent (SAIMR-B) (Liquid/Refrigerated) [173–181]:

1. Not field stable. Not broad-spectrum. Single species coverage.
2. Confirmed or suspected boomslang bite with no indications of improvement after 10 vials of POLYSERP-P. Monovalent that can only be used to treat the WHO category 2 boomslang. Does not provide coverage against any other WHO category 1 or category 2 species.
3. Initial dose = 2 vials boomslang only, additional doses = 1 vial as needed

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration. Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities in sub-Saharan Africa.

Adverse reactions: No clinical trials but effective anecdotally and in case reports. Moderate to high rates of anaphylaxis are anticipated based on limited case reports of patients treated with SAIMR-B.

Indications: This monovalent is only effective for the boomslang.

- Hemotoxic: *Dispholidus typus*

Initial dosing by syndrome:

- Not indicated for neurotoxic
- Hemotoxic with confirmed or suspected boomslang bite (typical onset coagulopathy and bleeding 1 – 3 days after the bite; no significant pain, swelling, or tissue destruction)
  - Initial dose = 2 vials SAIMR-B
  - POLYSERP-P should be the first line treatment for this species if available due to lower risk of allergic reactions.
- Not indicated for hemotoxic envenomation by snakes other than the boomslang
- Not indicated for cytotoxic

Additional dosing: Additional doses of 1 vial SAIMR-B may be repeated, if needed, at hours 2, 4, 6, 12, and 24 until cessation of all active bleeding or at 6, 12, and 24 for coagulopathy without bleeding.

Pretreatment: RECOMMENDED for this antivenom. Administer 0.25 mg epinephrine injected SQ prior to beginning antivenom infusion to reduce the risk of a serious reaction. Pediatric doses should be weight based at a dose of 0.01 mg/kg, up to 0.25 mg.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

SECOND LINE (AFRICOM - NORTH AFRICA): NAVPC-C

National Antivenom & Vaccine Production Center, Saudi Arabia - Polyvalent Snake Antivenom (NAVPC-P) (Liquid/Refrigerated)[182-186]:

Unknown neurotoxic, hemotoxic, or cytotoxic envenomation with no indications of improvement after 10 vials of POLYSERP-M. Directly or indirectly covers some of the WHO category 1 and category 2 snakes in this region for which an antivenom currently exists.

1. Not field stable. Broad-spectrum coverage 6+ species of Neuro/Hemo/Cyto.
2. Unknown neurotoxic, hemotoxic, or cytotoxic envenomation with no indications of improvement after 10 vials of POLYSERP-M. Directly or indirectly covers some of the WHO category 1 and category 2 snakes in this region for which an antivenom currently exists.
3. Initial dose neuro = 10 vials. Initial dose hemo/cyto = 5 vials. All additional doses = 5 vials.

Feasibility of use in austere environments: NOT RECOMMENDED for operational settings. Requires refrigeration, moderate to high rates of adverse reactions are anticipated. Better alternatives exist. If purchased, it should be kept at Role 2 & 3 facilities in the Arabian Peninsula.

Adverse reactions: Insufficient evidence to determine risk of adverse reactions at this time.

Indications: This polyvalent can be used to treat neurotoxic and cytotoxic envenomations by 6 different species of Middle Eastern, North African, and Central Asian snakes. It may be able to neutralize venom from additional species through paraspecific neutralization but this has not been researched.[187–192] The six species listed below are the official treatment indications recommended by the manufacturer:

- NEUROTOXIC: *Walterinnesia aegyptia, Naja haje*
- HEMOTOXIC and/or CYTOTOXIC: *Bitis arietans, Echis coloratus, Echis carinatus, Cerastes cerastes*

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 10 vials
- HEMOTOXIC initial dose = 5 vials
- CYTOTOXIC initial dose = 5 vials

Additional dosing: Additional doses of 5 vials NAVPC-C may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: Recommended for this antivenom due to insufficient evidence for determining risk of EARs. Administer 0.25 mg epinephrine injected SQ prior to beginning antivenom infusion to reduce the risk of a serious reaction. Pediatric doses should be weight based at a dose of 0.01 mg/kg, up to 0.25 mg.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

AFRICOM ANTIVENOM FORMULATION COMPARISON

Formulation, storage, stability, safety, and efficacy for six antivenoms available in the AFRICOM area of responsibility. EchiTAb-Plus is included for reference but is not recommended due to limited species coverage, low availability, and high rates of anaphylaxis.
Note: Specific indications according to the package insert.

Maximum temp allowed?	"Store between 2 – 8 ºC (35.6 – 46.4 ºF)"	"Excursions permitted to 40 ºC (104 ºF) for up to 6 months"	"Excursions permitted to 40 ºC (104 ºF) for up to 6 months"	"Store between 2 – 8 ºC (35.6 – 46.4 ºF)"	"Store between 2 – 8 ºC (35.6 – 46.4 ºF)"	"Store between 2 – 8 ºC (35.6 – 46.4 ºF)"
N of published cases	**n = 252** cases in retrospective studies that examined safety and efficacy; quality limited.	**n = 315** cases reported in prospective observational studies evaluating safety and efficacy under austere conditions.	**n = 426** cases reported in prospective observational studies evaluating safety and efficacy under austere conditions.	**n = 144** cases in retrospective / prospective studies (anecdotal and observational) that reported safety and efficacy data.	**n = 5** case reports but that included safety and efficacy data but no studies to date.	**n = 206 cases in RCT**

Efficacy in clinical studies	- Appears effective against most snakebites in North Africa / Arabian Peninsula; coverage is poor outside of this area due to differences in local species. May be less effective for DIC. - The **combined CFR all was 3.57%** (9/252); deaths were a mix of ICH, DIC, cardiac arrest, respiratory arrest. Most fatalities presented early.	- Effectively treated cytotoxic, hemotoxic, neurotoxic syndromes of SBE at hospitals throughout Morocco since the country switched to using it in 2015. - The **combined CFR all was 3.17%** (10/316); mostly of organ failure, hemorrhagic shock, sepsis after long treatment delays before presentation to the hospital.	- Effectively treated cytotoxic, hemotoxic, neurotoxic syndromes of SBE at poorly equipped rural health centers in Mali, Senegal, Benin, and Guinea. - The **combined CFR all was 1.6%** (7/426); mostly hemorrhagic shock from carpet viper bites in patients with long treatment delays before presentation to the hospital.	- Effectively treated cytotoxic, hemotoxic, neurotoxic syndromes of SBE at health centers in South Africa (5 studies) and Tanzania (1 study). - The **combined CFR was 3% (**5/144); two were neurotoxic envenomations and 3 were pediatric cases with unspecified syndromes.	- No clinical studies but very effective for resolving hemotoxic effects from boomslang envenomations in case reports.	- 3 vial dose effectively treated hemotoxic syndrome of SBE due to *Echis ocellatus* in Nigeria. Hemotoxic saw-scaled viper bites only; no evidence of efficacy for other snakes / syndromes. - There were no fatalities reported; however, patients with severe envenomations, late-presenting patients, and those complex cases were excluded from the study.
Safety *(incidence of anaphylaxis)*	Very limited data and all studies acknowledge likely underreporting of reactions. Most reliable study showed **moderate incidence of anaphylaxis 5.5% (2/36);** small sample.	**Very low incidence of anaphylaxis (1%; 3/290)** in 290 cases reported and evaluated by the poison center of Morocco. No cases of serum sickness.	**Very low incidence of anaphylaxis (0.2%; 1/426))** in prospective clinical studies. Only one case of possible anaphylaxis that is more consistent with shock from the snakebite. No cases of serum sickness.	**Very high incidence of anaphylaxis (average 26%; rate is as high as 76% in some studies).** Serum sickness not reported. Underreporting likely.	**Very high incidence of anaphylaxis (60%)** in the only study that evaluated at adverse reactions to SAIMR-B. One case of serum sickness.	**High incidence anaphylaxis (10.8%, n = 21/194)** and 5 cases of serum sickness reported.

CENTCOM

Treatment Guidelines

Safe and effective broad-spectrum, field-stable antivenoms are available for all three syndromes of snake envenomation in this AOR and treatment does not require identification of the species responsible. Snakebite treatment at the point of injury is recommended for CENTCOM due to potential for prolonged evacuation times, high incidence of snakebites, and the high risk of death or permanent disability from many venomous snakes in the AOR if early antivenom treatment is not available.

Adverse Reaction Management

- If a mild or moderate reaction occurs, slow the infusion and treat symptomatically with antihistamines, steroids, and/or antiemetics as needed.
- If a severe reaction such as anaphylaxis occurs, stop the infusion and treat according to the anaphylaxis protocol listed elsewhere in the CPG. Reassess the patient once the reaction has been controlled and resume the infusion at a slower rate if any of the specific criteria for antivenom treatment listed elsewhere in the CPG have not completely resolved.

Sudden Collapse Syndrome Treatment Protocol

Patient presents within 30 minutes of the bite with rapid onset shock ± angioedema, altered mental status, systemic bleeding, and diarrhea.[1]

1. Stabilize with IM or IV epinephrine and fluids as per anaphylaxis protocols
2. Intubate for airway edema not rapidly responsive to epinephrine
3. Follow epinephrine immediately with a high dose of the appropriate regional antivenom given by rapid IV or IO push during the resuscitation
4. Maintain blood pressure with IV or IO fluids and epinephrine until antivenom has taken effect to reverse the hypotension.

See Sudden Collapse Syndrome section for more information.

CONTACT

For emergency consultations, call the ADVISOR telemedicine hotline (866-972-9966) and select toxicology from the phone menu.

For additional information about snake bite management or this CPG, email jordan@snakebitefoundation.org or call 415-218-2211.

Table 5. CENTCOM - First Line Antivenoms

	Neurotoxic Syndrome	Hemotoxic Syndrome	Cytotoxic Syndrome
Mild	Local S/Sx (paresthesias; neuropathic pain; piloerection; muscle spasm, fasciculations)	Coagulopathy ± persistence of local bleeding from bite wound > 30 mins after bite	Severe pain; edema below elbow or knee; limited blistering within several inches of the bite wound
Moderate	Systemic S/Sx (bilateral ptosis GI symptoms; visual, auditory, or other sensory disturbances; widespread hyperesthesia)	Moderate systemic bleeding (old scabs, gingival bleeding, epistaxis, etc); bruising distant from the bite wound	Edema above elbow or knee but not beyond shoulder or hip; moderate local blistering along bitten limb segment
Severe	Difficulty speaking; altered mental status; respiratory muscle weakness causing difficulty breathing; shock or otherwise unstable patient	Active GI bleed (usually hematemesis) or other internal bleeding; severe anemia; altered mental status; shock or otherwise unstable patient	Progressive edema beyond shoulder or hip; severe necrosis or widespread blistering; symptomatic bite to head, neck, or torso; altered mental status; shock or otherwise unstable patient
Criteria for additional AV doses at hours 2, 4, 6, 12, 24 (as needed)	Additional doses if: persistence or worsening of systemic neurotoxic S/Sx. Continue to re-administer 2 vial boluses as needed at hours 2, 4, 6, 12, and 24 until indications of improvement begin to appear (↑SBC, ↑LOC, ↑strength, etc.)	Additional doses if: persistence, resumption, or new onset of any active external or internal bleeding **OR** S/Sx of active venom confirmed by secondary recurrence of abnormal WBCT	Additional doses if: significant increase in edema (such as beyond major joint) **OR** significant increase in pain (severity of pain and/or how far pain radiates up the bitten limb)
CENTCOM 1st Line Antivenoms	CENTCOM: Broad-spectrum coverage for all neurotoxic/hemotoxic/cytotoxic snakebite syndromes by known* or unknown species - POLYSERP-M: Initial dose = 6 vials regardless of severity / Additional doses = 2 vials as needed Central Asia: *If patient has a confirmed Gloydius halys bite (rare!), use SIOBP-G as 1st line if available. FIRST LINE CENTCOM - Arabian Peninsula/Middle East/Central Asia: POLYSERP-M

POLYSERP / Inosan, Spain - POLYSERP MENA Polyvalent (POLYSERP-M) (Freeze dried/Unrefrigerated) [162–172]

1. Field-stable. Broad-spectrum coverage 27+ species of Cyto/Hemo/Neuro.
2. Single source treatment option for all neurotoxic, hemotoxic, and cytotoxic snake envenomations in the Arabian Peninsula, the Middle East, and Central Asia when the causative species is either unknown or among the 27 snakes for which this product is directly indicated. Directly or indirectly covers all WHO category 1 species in the region. Directly or indirectly covers all category 2 snakes in this region for which an antivenom currently exists except for *Gloydius halys*, which is covered by Shanghai SIOBP-G or Iranian RAZI-P. Paraspecific neutralization against *Gloydius* unknown but not anticipated.
3. Initial dose = 6 vials all syndromes, additional doses = 2 vials as needed.

Feasibility of use in austere environments: Recommended for use in operational settings and specifically designed to fill the capability gap for ground medics operating in these areas. Updated version of Inoserp MENA made specifically for the austere and operational medicine environment. Freeze-dried, unrefrigerated, stable at temperatures >100º F for at least 180 days without loss of efficacy. Broad coverage and simple dosing enable administration in the field for any symptomatic snakebite by unknown species in this region. Special operations and conventional units deploying to austere operational environments and areas with critical threat venomous species should carry 8 vials per medic. It is recommended that a reserve quantity is stocked in all role 2 and role 3 facilities in AFRICOM in case additional antivenom is needed upon arrival, and also to restock field medics that have used their supply.

Adverse reactions: High efficacy against all major syndromes and low incidence of serious adverse reactions of approximately 1% based on current publications.

Indications: Broad spectrum polyvalent directly indicated for the treatment of neurotoxic, hemotoxic, and cytotoxic envenomation syndromes caused by 27 different species of Middle Eastern, North African, and Central Asian snakes from the families *Elapidae* and *Viperidae*. First line for snake envenomations in this region when the causative species is unknown or among the species for which the product is directly indicated.

- NEUROTOXIC: Naja haje, N. oxiana; Walterinnesia aegyptia
- CYTOTOXIC and/or HEMOTOXIC: *Bitis arietans; Cerastes cerastes, C. vipera, C. gasperettii; Daboia palestinae, D. mauritanica, D. deserti; Echis. carinatus sochureki, E. coloratus, E. khosatskii, E. leucogaster, E. megalocephalus, E. omanensis, E. pyramidum; Macrovipera lebetina obtusa, M. l. transmediterranea, M. l. turanica; Montivipera bornmuelleri, M. raddei kurdistanica; Naja nubiae, N. pallida; Pseudocerastes persicus persicus, P. fieldi; Vipera latastei*

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 6 vials
- HEMOTOXIC initial dose = 6 vials
- CYTOTOXIC initial dose = 6 vials

Additional dosing: Additional doses of 2 vials POLYSERP-M may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Reconstitute every 2 vials of POLYSERP-M in the same 10 mL syringe by mixing the first vial, drawing it back up into syringe, and injecting it into the second vial to yield 2 vials/1 syringe (6 vial dose = 3 syringes total). Administer sequentially via slow, continuous direct IV or IO push over approximately 2

minutes each. If a reaction occurs stop the push, treat the reaction, reassess response to treatment criteria. Dilute remaining dose in a 100 mL bag of isotonic fluids and administer via slow IV or IO infusion over 30 mins if needed.

Direct push is recommended for convenience, but POLYSERP-M may also be administered via IV or IO infusion. Mix in a 50 mL or 100 mL bag of isotonic fluids and administer the entire bag over 5 – 10 mins.

FIRST LINE & SECOND LINE CENTCOM - Middle East/Central Asia: SIOBP-G

Shanghai Institute of Biological Products, China - Agkistrodon (Gloydius) halys Monovalent Antivenom (SIOBP-G): (Liquid/Refrigerated)[194–196]:

NOTE: This product is listed as Agkistrodon halys on the SIOBP website and product packaging but the taxonomy for this species has changed. Agkistrodon halys was moved to the genus *Gloydius* and should be listed as Gloydius *halys* as it is listed elsewhere. The product is abbreviated as SIOBP-G in the CPGs to account for this correction.

1. Not field stable. Not broad-spectrum. Single species coverage.
2. Monovalent for the WHO category 2 species *Gloydius halys*. Indicated as first line only for confirmed envenomation by *Gloydius halys* or related *Gloydius* species. Indicated as second line for unknown cytotoxic and/or hemotoxic envenomation in Middle East or Central Asia with no signs of improvement after 10 vials of POLYSERP-M. Does not provide coverage against any other WHO category 1 or category 2 species.
3. Initial dose = 6 vials hemotoxic/cytotoxic only, additional doses = 2 vials as needed.

First line (CENTCOM - MIDDLE EAST / CENTRAL ASIA): Monovalent for the WHO category 2 species *Gloydius halys.* Indicated only for confirmed envenomation by *Gloydius halys* or related *Gloydius* species. Does not provide coverage against any other WHO category 1 or category 2 species.

Second line (CENTCOM - MIDDLE EAST / CENTRAL ASIA): Indicated for unknown cytotoxic and/or hemotoxic envenomation in Middle East or Central Asia with no signs of improvement ***after 10 vials of POLYSERP-M.***

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration. Recommend storing small quantities at strategically located Role 2 & 3 facilities in CENTCOM AOR.

Incidence of adverse reactions: Low to moderate rates of EARs and serum sickness are anticipated but clinical evidence is limited.

Indications: This monovalent can be used to treat cytotoxic and hemotoxic envenomations by *Gloydius halys*, a pit viper native to the Middle East and Central Asia. It will most likely neutralize venom from related species in the genus Gloydius through paraspecificity, but this has not been tested in detail. There are several publications indicating that it may also have paraspecificity against some of the Southeast Asian green pit vipers from the genera *Cryptelytrops* and *Trimeresurus.*[196,197] However, it is not currently indicated by the manufacturer for these species.

- HEMOTOXIC AND/OR CYTOTOXIC: *Gloydius halys*

Initial dosing by syndrome:

- NOT INDICATED FOR NEUROTOXIC
- HEMOTOXIC initial dose = 2 vials
- CYTOTOXIC initial dose = 2 vials

Additional dosing: Additional doses of 2 vials SIOBP-G may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

SECOND LINE CENTCOM - Middle East/Central Asi): RAZI-P

Razi Serum and Vaccine Research Institute, Islamic Republic of Iran - Polyvalent Snake Antivenom (RAZI-P) (Liquid/refrigerated)[198-205]**:**

1. Not field stable. Broad-spectrum coverage 6+ species Cyto/Hemo/Neuro.
2. Unknown neurotoxic, hemotoxic, or cytotoxic envenomation with no indications of improvement after 10 vials of POLYSERP-M. Directly or indirectly covers all WHO category 1 species in the region. Directly or indirectly covers some of the WHO category 1 and category 2 snakes in this region for which an antivenom currently exists.

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration. Recommend storing small quantities at strategically located Role 2 & 3 facilities in CENTCOM AOR or selecting alternative second line from this CPG.

Adverse reactions: Limited evidence but appears to be low based on current publications.

Indications: This polyvalent can be used to treat neurotoxic and cytotoxic envenomations by 6 different species of Middle Eastern, North African, and Central Asian snakes. It may be able to neutralize venom from additional species through paraspecific neutralization, but this has not been researched. The 6 species listed below are the official treatment indications recommended by the manufacturer:

- NEUROTOXIC: *Naja oxiana*
- HEMOTOXIC and/or CYTOTOXIC: *Pseudocerastes persicus fieldi, Echis carinatus, Vipera albicornuta, Vipera lebetina obtusa, Agkistrodon (Gloydius) halys*

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met.

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 10 vials
- HEMOTOXIC initial dose = 5 vials
- CYTOTOXIC initial dose = 5 vials

Additional dosing: Additional doses of 5 vials RAZI-P may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

SECOND LINE CENTCOM - Arabian Peninsula: NAVPC-C

National Antivenom & Vaccine Production Center, Saudi Arabia - Polyvalent Snake Antivenom (NAVPC-P) (Liquid/Refrigerated) [187-192] :

1. Not field stable. Broad-spectrum coverage 6+ species of Neuro/Hemo/Cyto.
2. Unknown neurotoxic, hemotoxic, or cytotoxic envenomation with no indications of improvement after 10 vials of POLYSERP-M. Only for Arabian Peninsula, very limited utility further East. Directly or indirectly covers some of the WHO category 1 and category 2 snakes in this region for which an antivenom currently exists.
3. Initial dose neuro = 10 vials. Initial dose hemo/cyto = 5 vials. All additional doses = 5 vials.

Feasibility of use in austere environments: Not recommended for operational settings. Requires refrigeration, moderate to high rates of adverse reactions are anticipated. Better alternatives exist. If purchased, it should be kept at Role 2 & 3 facilities in the Arabian Peninsula.

Adverse reactions: Insufficient evidence to determine risk of adverse reactions at this time.

Indications: This polyvalent can be used to treat neurotoxic and cytotoxic envenomations by 6 different species of Middle Eastern, North African, and Central Asian snakes. It may be able to neutralize venom from additional species through paraspecific neutralization, but this has not been researched. The 6 species listed below are the official treatment indications recommended by the manufacturer:

- NEUROTOXIC: *Walterinnesia aegyptia, Naja haje*
- HEMOTOXIC and/or CYTOTOXIC: *Bitis arietans, Echis coloratus, Echis carinatus, Cerastes cerastes*

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 10 vials
- HEMOTOXIC initial dose = 5 vials
- CYTOTOXIC initial dose = 5 vials

Additional dosing: Additional doses of 5 vials NAVPC-C may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: RECOMMENDED for this antivenom due to insufficient evidence for determining risk of EARs. Administer 0.25 mg epinephrine injected SQ prior to beginning antivenom infusion to reduce the risk of a serious reaction. Pediatric doses should be weight based at a dose of 0.01 mg/kg, up to 0.25 mg.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

EUCOM

Treatment Guidelines

Safe and effective broad-spectrum, refrigerated antivenoms are available for all three syndromes of snake envenomation due to European viper species in this AOR and treatment does not require identification of the species responsible. Snakebite treatment at the point of injury is not routinely recommended for EUCOM. This section provides specifics about antivenoms use in this region

ADVERSE REACTION MANAGEMENT

- If a mild or moderate reaction occurs, slow the infusion and treat symptomatically with antihistamines, steroids, and/or antiemetics as needed.
- If a severe reaction such as anaphylaxis occurs, stop the infusion and treat according to the anaphylaxis protocol listed elsewhere in the CPG. Reassess the patient once the reaction has been controlled and resume the infusion at a slower rate if any of the specific criteria for antivenom treatment listed elsewhere in the CPG have not completely resolved.

Sudden Collapse Syndrome Treatment Protocol

Patient presents within 30 minutes of the bite with rapid onset shock ± angioedema, altered mental status, systemic bleeding, and diarrhea.[1]

4. Stabilize with IM or IV epinephrine and fluids as per anaphylaxis protocols
5. Intubate for airway edema not rapidly responsive to epinephrine
6. Follow epinephrine immediately with a high dose of the appropriate regional antivenom given by rapid IV or IO push during the resuscitation
7. Maintain blood pressure with IV or IO fluids and epinephrine until antivenom has taken effect to reverse the hypotension.

See Sudden Collapse Syndrome section for more information.

CONTACT

For emergency consultations, call the ADVISOR telemedicine hotline (866-972-9966) and select toxicology from the phone menu.

For additional information about snake bite management or this CPG, email jordan@snakebitefoundation.org or call 415-218-2211.

Table 6. EUCOM First Line Antivenoms

	Neurotoxic Syndrome	Hemotoxic Syndrome	Cytotoxic Syndrome
Mild	Local S/Sx (paresthesias; neuropathic pain; piloerection; muscle spasm, fasciculations)	Coagulopathy ± persistence of local bleeding from bite wound > 30 mins after bite	Severe pain; edema below elbow or knee; limited blistering within several inches of the bite wound
Moderate	Systemic S/Sx (bilateral ptosis GI symptoms; visual, auditory, or other sensory disturbances; widespread hyperesthesia)	Moderate systemic bleeding (old scabs, gingival bleeding, epistaxis, etc.); bruising distant from the bite wound	Edema above elbow or knee but not beyond shoulder or hip; moderate local blistering along bitten limb segment
Severe	Difficulty speaking; altered mental status; respiratory muscle weakness causing difficulty breathing; shock or otherwise unstable patient	Active GI bleed (usually hematemesis) or other internal bleeding; severe anemia; altered mental status; shock or otherwise unstable patient	Progressive edema beyond shoulder or hip; severe necrosis or widespread blistering; symptomatic bite to head, neck, or torso; altered mental status; shock or otherwise unstable patient
Criteria for additional AV doses at hours 2, 4, 6, 12, 24 (as needed)	*Additional doses if:* *persistence or worsening of systemic neurotoxic S/Sx. Continue to re-administer 2 vial boluses as needed at hours 2, 4, 6, 12, and 24 until signs of improvement begin to appear* (↑SBC, ↑LOC, ↑strength, etc.)	*Additional doses if:* *persistence, resumption, or new onset of any active external or internal bleeding* ***OR*** *S/Sx of active venom confirmed by secondary recurrence of abnormal WBCT*	*Additional doses if:* *significant increase in edema (such as beyond major joint)* ***OR*** *significant increase in pain (severity of pain and/or how far pain radiates up the bitten limb)*
EUCOM 1st Line Antivenoms	UK or Scandinavia**:** Broad-spectrum coverage all neurotoxic/hemotoxic/cytotoxic syndromes from European Vipera species - VIPERATAB (1st line): Initial dose = 2 vials (one box), additional doses = 1 – 2 vials as needed - VIPERFAV (2nd line): Initial dose = 1 – 2 vials, additional doses = 1 vial as needed Outside UK/Scandinavia: Broad-spectrum coverage all neurotoxic/hemotoxic/cytotoxic syndromes from European Vipera species - VIPERFAV (1st line): Initial dose = 1 – 2 vials, additional doses = 1 vial as needed - VIPERATAB (2nd line): Initial dose = 2 vials (one box), additional doses = 1 – 2 vials as needed

FIRST LINE EUCOM - Outside UK/Scandinavia: VIPERFAV

SECOND LINE EUCOM - Inside UK/Scandinavia: VIPERFAV

Sanofi-Pasteur, France - Viperfav (VIPERFAV) (Freeze dried/Refrigerated) [206-212]:

1. Not field-stable. Broad-spectrum coverage against multiple European vipers.
2. **First line treatment option (EUCOM - EUCOM OUTSIDE UK / SCANDINAVIA)**: Single-source treatment option for neurotoxic, hemotoxic, and cytotoxic snake envenomations by the most medically and epidemiologically significant species in Europe (*Vipera berus, V. aspis, V. ammodytes*) with paraspecific coverage against other European Vipera species. Can be used in the EUCOM AOR when the causative species is unknown or species for which this product is directly indicated.
3. **Second line treatment option (EUCOM - UK / SCANDINAVIA)** for all neurotoxic, hemotoxic, and cytotoxic snake envenomations within the UK and Scandinavia if first line (VIPERATAB) is not available.
4. Initial dose = 1 – 2 vials all syndromes, additional doses = 1 vial as needed.

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration between 2 - 8 ºC (35.6 - 46.4 ºF). Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities. Likely to retain efficacy for several weeks in the field but should be disposed of after that duration of time outside refrigeration.

Adverse reactions: High efficacy against all major syndromes and low incidence of serious adverse reactions based on current publications.

Indications: Polyvalent antivenom directly indicated for the treatment of neurotoxic, hemotoxic, and cytotoxic envenomation syndromes caused by *Vipera berus, V. aspis, V. ammodytes* but has demonstrated efficacy against other species of European vipers (genus Vipera) as well.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 2 vials
- HEMOTOXIC initial dose = 1 - 2 vials
- CYTOTOXIC initial dose = 1 - 2 vials

Additional dosing: Additional doses of 1 vial VIPERFAV may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE EUCOM – Inside UK/Scandinavia: VIPERATAB

SECOND LINE EUCOM – Outside UK/Scandinavia: VIPERATAB

Micropharm, UK - ViperaTAb (VIPERATAB) (Freeze dried/Refrigerated) [206,210,213–215]:

1. Not field stable. Broad-spectrum coverage against several European vipers.
2. **First line (EUCOM - UK / SCANDINAVIA):** Single-source treatment option for neurotoxic, hemotoxic, and cytotoxic snake envenomations by the most medically and epidemiologically significant species in the UK and Scandinavia (Vipera berus) with paraspecific coverage against some other European Vipera species.
3. **Second line treatment option (EUCOM - OUTSIDE OF UK / SCANDINAVIA)** for all neurotoxic, hemotoxic, and cytotoxic snake envenomations in the EUCOM AOR outside of the UK and Scandinavia if first line (VIPERFAV) is not available.
4. Initial dose = 2 vials all syndromes, additional doses = 2 vials as needed. Each box = 2 vials.

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration between 2 - 8 ºC (35.6 - 46.4 ºF). Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities. Likely to retain efficacy for several weeks in the field but should be disposed of after that duration of time outside refrigeration.

Adverse reactions: High efficacy against UK / Scandinavian European viper (*Vipera berus*) envenomations and low incidence of serious adverse reactions based on current publications.

Indications: Polyvalent antivenom directly indicated for the treatment of neurotoxic, hemotoxic, and cytotoxic envenomation syndromes caused by *Vipera berus*. Has demonstrated efficacy against other species of European vipers (*V. aspis, V. ammodytes*) as well but is not directly indicated for these species.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 2 vials
- HEMOTOXIC initial dose = 2 vials
- CYTOTOXIC initial dose = 2 vials

Additional dosing: Additional 2 vials VIPERATAB may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Each box of VIPERATAB comes with two 4 mL vials of antivenom (one box = one dose). Dilute the entire dose of antivenom in a single 100 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

INDOPACOM
Treatment Guidelines

Safe and effective broad-spectrum, field-stable antivenoms are available for all three syndromes of snake envenomation in Southeast Asia and several other areas within this AOR. Snakebite treatment in INDOPACOM as a whole is more complex than AFRICOM or CENTCOM due to the lack of a truly pan-Asian polyvalent product. Treatment in many places does not require identification of the species responsible, but products are syndrome specific and there is no single product for all 3 syndromes. Snakebite treatment at the point of injury is recommended for areas within the INDOPACOM AOR where field-stable antivenoms are available. This section provides specifics about antivenoms use in this region.

ADVERSE REACTION MANAGEMENT

- If a mild or moderate reaction occurs, slow the infusion and treat symptomatically with antihistamines, steroids, and/or antiemetics as needed.
- If a severe reaction such as anaphylaxis occurs, stop the infusion, and treat according to the anaphylaxis protocol listed elsewhere in the CPG. Reassess the patient once the reaction has been controlled and resume the infusion at a slower rate if any of the specific criteria for antivenom treatment listed elsewhere in the CPG have not completely resolved.

Sudden Collapse Syndrome Treatment Protocol

Patient presents within 30 minutes of the bite with rapid onset shock ± angioedema, altered mental status, systemic bleeding, and diarrhea.[1]

1. Stabilize with IM or IV epinephrine and fluids as per anaphylaxis protocols
2. Intubate for airway edema not rapidly responsive to epinephrine
3. Follow epinephrine immediately with a high dose of the appropriate regional antivenom given by rapid IV or IO push during the resuscitation
4. Maintain blood pressure with IV or IO fluids and epinephrine until antivenom has taken effect to reverse the hypotension.

See Sudden Collapse Syndrome section for more information.

FIRST LINE INDOPACOM - Southeast Asia: TRC-HPAV

Thai Red Cross, Thailand - Hemato Polyvalent Antivenom (TRC-HPAV) (Freeze dried/Unrefrigerated) [62,196, 197, 216–218]:

1. Field-stable. Broad-spectrum coverage multiple species of Hemo/Cyto.
2. Broad-spectrum treatment option for all hemotoxic and cytotoxic snake envenomations by known or unknown species in Southeast Asia. Best regional polyvalent.
3. Initial dose hemotoxic/cytotoxic only = 10 vials, additional doses = 5 vials as needed.

Feasibility of use in austere environments: Recommended for operational settings. Unrefrigerated storage at ambient tropical temperatures of ≤ 25º C / 77º F. Lyophilized product that likely retains stability at higher temperatures for short excursions (likely up to several months). Recommend carrying full dose into field on extended operations in austere environments and storing larger quantities at strategically located Role 2 & 3 facilities in INDOPACOM AOR.

Adverse reactions: High efficacy against and low incidence of serious adverse reactions based on current publications.

Indications: Polyvalent antivenom directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by *Calloselasma rhodostoma, Trimersurus albolabris*, and *Daboia russelli siamensis.* Has demonstrated efficacy against other related species of Asian vipers within the same genera (Crytelytrops, Popeia, Daboia, etc.); is not directly indicated for these species but is the best hemotoxic / cytotoxic polyvalent in the region and should be tried as first line in most cases.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NOT INDICATED FOR NEUROTOXIC
- HEMOTOXIC initial dose = 10 vials
- CYTOTOXIC initial dose = 10 vials

Additional dosing: Additional 2 vials TRC-HPAV may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE INDOPACOM - Southeast Asia Broad Spectrum Neurotoxic: TRC-NPAV

Thai Red Cross, Thailand - Neuro Polyvalent Antivenom (TRC-NPAV) (Freeze dried/Unrefrigerated) [62,196,217,219–221,]:

1. Field-stable. Broad-spectrum coverage multiple species of Neuro.
2. Broad-spectrum treatment option for all neurotoxic snake envenomations by known or unknown species in Southeast Asia. Best regional polyvalent.
3. Initial dose = 10 vials neurotoxic only, additional doses = 5 vials as needed.

Feasibility of use in austere environments: Recommended for operational settings. Unrefrigerated storage at ambient tropical temperatures of ≤ 25º C / 77º F. Lyophilized product that likely retains stability at higher temperatures for field excursions (likely stable for several months at higher temps based on data from similar

products). Recommend carrying full dose into field on extended operations in austere environments and storing larger quantities at strategically located Role 2 & 3 facilities in INDOPACOM AOR.

Adverse reactions: High efficacy and low incidence of serious adverse reactions based on current publications.

Indications: Polyvalent antivenom directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by *Ophiophagus hannah, Naja kaouthia, Bungarus candidus,* and *B. fasciatus candidus*. Has demonstrated efficacy against other related species of Asian cobras and kraits; is not directly indicated for these species but is the best hemotoxic / cytotoxic polyvalent in the region and should be tried as the first line in most cases.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 10 vials
  ***NOTE**: King cobra (O. hannah) bites likely to require much higher doses of antivenom due to massive venom yield; it is not unusual to require dozens of vials in these cases.*
- NOT INDICATED FOR HEMOTOXIC
- NOT INDICATED FOR CYTOTOXIC

Additional dosing: Additional 5 vials TRC-NPAV may be given at hours 2, 4, 6, 12, and 24 if needed. Bites from large king cobras may require several dozen vials or more due to massive venom yield.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE INDOPACOM – Taiwan/Southeast China/N Laos/N Vietnam: NIPM-NBB

National Institute Preventative Medicine, Taiwan - *Naja atra* / *Bungarus multicinctus* Bivalent (NIPM-NBB) (Freeze dried/Refrigerated) [222–230]:

1. Liquid product but field-stable for short excursions. Broad-spectrum coverage multiple species of Neuro.
2. Bivalent treatment option for neurotoxic cobra and krait envenomations in East Asia.
3. Initial dose = 5 vials neurotoxic only, additional doses = 5 vials as needed.

Feasibility of use in austere environments: Conditionally recommended for operational settings during short excursions. Lyophilized but requires cold chain refrigeration below 10ºC (50 ºF); however, testing by Taiwanese CDC showed no loss of potency after 30 days of incubation at 35º C / 95º F and also after it was returned to refrigerated storage for 4 months thereafter. Recommend carrying full dose into field on extended operations in austere environments and storing larger quantities at regional Role 2 & 3 facilities.

Adverse reactions: High efficacy and low incidence of serious adverse reactions based on current publications.

Indications: Polyvalent antivenom directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by *Naja atra* and *Bungarus multicinctus.* Has demonstrated efficacy against other related species of Asian cobras and kraits but is not directly indicated for these species.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NEUROTOXIC initial dose = 5 vials
- NOT INDICATED FOR HEMOTOXIC
- NOT INDICATED FOR CYTOTOXIC

Additional dosing: Additional 5 vials NIPM-NBB may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 100 – 500 mL bag of isotonic solution and administer by intravenous infusion over 10 – 30 minutes.

FIRST LINE INDOPACOM - Japan: CSTRI-HABU

Chemo-Sero Therapeutic Research Institute, Japan - Kaketsuken Habu Antivenom (CSTRI-HABU)
(Freeze dried/Refrigerated) [231–235]:

1. Not field-stable. Not broad-spectrum. Habu coverage only.
2. First line treatment option for Habu envenomation (Protobothrops spp.).
3. Initial dose = 1 – 2 vials, additional doses = 1 vial as needed

Feasibility of use in austere environments: Not recommended for operational settings. Lyophilized but requires cold chain refrigeration below 10ºC (50 ºF); likely to retain efficacy for short excursions lasting several weeks in the field but should be disposed of and replaced after extended time outside refrigeration. Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities.

Adverse reactions: High efficacy and low incidence of serious adverse reactions based on current publications.

Indications: Directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by the Japanese Habu (*Protobothrops [Trimeresurus] flavoviridis*)

Pretreatment: Not routinely Indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met; however, total reactions (~11% overall; ~25% serum sickness) higher than other regional products. Consider pretreatment on an individual basis.

Initial dosing by syndrome:

- NOT INDICATED FOR NEUROTOXIC
- HEMOTOXIC = 1 - 2 vials
- CYTOTOXIC = 1 - 2 vials

Additional dosing: Additional 1 vial CSTRI-HABU may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE INDOPACOM - Japan: CSTRI-MAMU

Chemo-Sero Therapeutic Research Institute, Japan - Kaketsuken Mamushi Antivenom (CSTRI-MAMU)
(Freeze dried/Refrigerated) [231–235]:

1. Not field stable. Not broad-spectrum. Japanese Mamushi coverage only.
2. First line treatment option for hemotoxic and cytotoxic envenomation syndromes caused by the Japanese Mamushi (*Gloydius blomhoffi*).

3. Initial dose = 1 – 2 vials, additional doses = 1 vial as needed

Feasibility of use in austere environments: Not recommended for operational settings. Lyophilized but requires cold chain refrigeration below 10ºC (50 ºF); likely to retain efficacy for short excursions lasting several weeks in the field but should be disposed of and replaced after extended time outside refrigeration. Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities.

Adverse reactions: High efficacy and low incidence of serious adverse reactions based on current publications.

Indications: Directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by the Japanese Mamushi, *Gloydius blomhoffi*.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NOT INDICATED FOR NEUROTOXIC
- HEMOTOXIC = 1 - 2 vials
- CYTOTOXIC = 1 - 2 vials

Additional dosing: Additional 1 vial CSTRI-MAMU may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE (INDOPACOM – Japan/China/N Korea/S Korea/Vietnam/E Russia): JSI-AYA

Japan Snake Institute, Japan - Anti-Yamakagashi Antivenom (JSI-AYA) (Freeze dried/Refrigerated) [231–233]:

1. Not field stable. Not broad-spectrum. Keelback coverage only.
2. First line treatment option for hemotoxic and cytotoxic envenomation syndromes caused by the Tiger Keelback (*Rhabdophis tigrinus*) and other East Asian keelback species.
3. Initial dose = 1 – 2 vials, additional doses = 1 vial as needed

Feasibility of use in austere environments: Not recommended for operational settings. Lyophilized but requires cold chain refrigeration below 10ºC (50 ºF); likely to retain efficacy for short excursions lasting several weeks in the field but should be disposed of and replaced after extended time outside refrigeration. Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities.

Adverse reactions: High efficacy and low incidence of serious adverse reactions based on current publications.

Indications: Directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by the Tiger Keelback (*Rhabdophis tigrinus*) and other East Asian keelbacks.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NOT INDICATED FOR NEUROTOXIC
- HEMOTOXIC = 1 - 2 vials
- CYTOTOXIC = 1 - 2 vials

Additional dosing: Additional 1 vial JSI-AYA may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE (INDOPACOM - N Korea/S Korea/E. China): KOVAX-AKA

Korea Vaccine, Korea - Agkistrodon Mamushi Antivenom (KOVAX-AKA) (Freeze dried/Refrigerated) [234–240]:

1. Not field stable. Not broad-spectrum. Korean Mamushi coverage only.
2. First line treatment option of hemotoxic and cytotoxic envenomation syndromes caused by the major species of Mamushi in the Korean Peninsula (*Gloydius brevicaudus, G. ussuriensis, G. intermedius*). May neutralize other related species.
3. Initial dose = 1 – 2 vials, additional doses = 1 vial as needed

Feasibility of use in austere environments: Not recommended for operational settings. Lyophilized but requires cold chain refrigeration below 10ºC (50 ºF); likely to retain efficacy for short excursions lasting several weeks in the field but should be disposed of and replaced after extended time outside refrigeration. Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities.

Adverse reactions: High efficacy and low incidence of serious adverse reactions based on current publications.

Indications: Directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by the major species of Mamushi in the Korean Peninsula (*Gloydius brevicaudus, G. ussuriensis, G. intermedius*). May neutralize other related species.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NOT INDICATED FOR NEUROTOXIC
- HEMOTOXIC = 1 - 2 vials
- CYTOTOXIC = 1 - 2 vials

Additional dosing: Additional 1 vial KOVAX-AKA may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE (INDOPACOM - Taiwan/SE China/N Vietnam/Laos): NIPM-SNV

National Institute Preventative Medicine, Taiwan - Sharp-nosed Viper Monovalent (NIPM-SNV) (Freeze dried/Refrigerated) [223,235–240:]

1. Freeze-dried product requiring cold chain but likely to be field-stable for short excursions. Not broad-spectrum. Sharp-nosed viper only.
2. First line monovalent antivenom directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by the sharp-nosed viper (*Deinagkistrodon acutus*).
3. Initial dose = 2 vials, additional doses = 1 vial as needed

Feasibility of use in austere environments: Conditionally recommended for operational settings during short excursions. Lyophilized but requires cold chain refrigeration below 10ºC (50 ºF); however, testing by Taiwanese

CDC showed no loss of potency after 30 days of incubation at 35º C / 95º F and also after it was returned to refrigerated storage for 4 months thereafter. Recommend carrying full dose into field on extended operations in austere environments and storing larger quantities at regional Role 2 and 3 facilities.

Adverse reactions: High efficacy and low incidence of serious adverse reactions based on current publications.

Indications: Monovalent antivenom directly indicated for the treatment of hemotoxic and cytotoxic envenomation syndromes caused by *Deinagkistrodon acutus*.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Initial dosing by syndrome:

- NOT INDICATED FOR NEUROTOXIC
- HEMOTOXIC initial dose = 2 vials
- CYTOTOXIC initial dose = 2 vials

Additional dosing: Additional 1 vials NIPM-SNV may be given at hours 2, 4, 6, 12, and 24 if needed.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE (INDOPACOM – Marine Environments Only): CSL-SS

Commonwealth Serum Laboratories, Australia - Sea Snake (CSL-SS) (Liquid/Refrigerated) [231-245] :

1. Not field stable. Broad-spectrum coverage against Indo-Pacific sea snakes only.
2. Neurotoxic envenomation in INDOPACOM by sea snakes or unknown species occurring in a strictly marine environment.
3. Initial dose = 3 vials, additional doses = 1 vial as needed

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration between 2 - 8 ºC (35.6 - 46.4 ºF). Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities. Likely to retain efficacy for several weeks in the field but should be disposed of after that duration of time outside refrigeration.

Adverse reactions: High-quality product with low rates of reactions anticipated.

Indications: This polyvalent can be used to treat neurotoxic envenomations by most major species of sea snakes in Australasia.

Initial dosing by syndrome:

- NEUROTOXIC syndrome initial dose = 3 vials
- NOT INDICATED for hemotoxic envenomations
- NOT INDICATED for cytotoxic envenomations

Additional dosing: Additional doses of 1 vials CSL-SS may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE (INDOPACOM – Maluku/West Papua Islands only): CSL-P

Commonwealth Serum Laboratories, Australia - Polyvalent (CSL-P) (Liquid/Refrigerated) [61, 241, 245-248]:

1. Not field stable. Broad-spectrum coverage.
2. First line antivenom indicated for neurotoxic/hemotoxic envenomation in INDOPACOM by Australasian elapids or unknown species occurring East of Wallace's line.
3. Initial dose = 3 vials, additional doses = 1 vial as needed

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration between 2 - 8 ºC (35.6 - 46.4 ºF). Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities. Likely to retain efficacy during short excursion at higher temperatures for several weeks in the field but should be disposed of and replaced afterwards.

Adverse reactions: High-quality product with low rates of reactions anticipated.

Indications: This polyvalent can be used to treat neurotoxic envenomations by the most medically significant species of Australasian elapid snakes found East of Wallace's line.

Initial dosing by syndrome:

- NEUROTOXIC syndrome initial dose = 3 vials
- HEMOTOXIC syndrome initial dose = 3 vials
- NOT INDICATED FOR CYTOTOXIC ENVENOMATIONS

Additional dosing: Additional doses of 1 vials CSL-P may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

NORTHCOM
Treatment Guidelines

Safe and effective antivenoms are available for all neurotoxic/hemo/cytotoxic pit viper envenomations and for neurotoxic coral snake envenomations in this AOR. Treatment does not require identification of the species responsible. Snakebite treatment at the point of injury is not routinely recommended for NORTHCOM.

For all NORTHCOM antivenoms, refer to the package insert in the antivenom box for specific usage instructions as per FDA regulations for domestically approved products. Also see Unified treatment algorithm for the management of crotaline snakebite in the U.S. (Lavonas et al. 2011) for dosing and management guidelines on pit viper bites.[101] This section provides specifics about antivenoms use in this region.

Adverse Reaction Management

- If a mild or moderate reaction occurs, slow the infusion, and treat symptomatically with antihistamines, steroids, and/or antiemetics as needed.
- If a severe reaction such as anaphylaxis occurs, stop the infusion, and treat according to the anaphylaxis protocol listed elsewhere in the CPG. Reassess the patient once the reaction has been controlled and resume the infusion at a slower rate if any of the specific criteria for antivenom treatment listed elsewhere in the CPG have not completely resolved.

Sudden Collapse Syndrome Treatment Protocol

Patient presents within 30 minutes of the bite with rapid onset shock ± angioedema, altered mental status, systemic bleeding, and diarrhea.[1]

1. Stabilize with IM or IV epinephrine and fluids as per anaphylaxis protocols
2. Intubate for airway edema not rapidly responsive to epinephrine
3. Follow epinephrine immediately with a high dose of the appropriate regional antivenom given by rapid IV or IO push during the resuscitation
4. Maintain blood pressure with IV or IO fluids and epinephrine until antivenom has taken effect to reverse the hypotension.

See Sudden Collapse Syndrome section for more information.

CONTACT

For emergency consultations, call the ADVISOR telemedicine hotline (866-972-9966) and select toxicology from the phone menu.

For additional information about snake bite management or this CPG, email jordan@snakebitefoundation.org or call 415-218-2211.

Table 8. NORTHCOM- First Line Antivenoms

	Neurotoxic Syndrome	Hemotoxic Syndrome	Cytotoxic Syndrome
Mild	Local S/Sx (paresthesias; neuropathic pain; piloerection; muscle spasm, fasciculations)	Coagulopathy ± persistence of local bleeding from bite wound > 30 mins after bite	Severe pain; edema below elbow or knee; limited blistering within several inches of the bite wound
Moderate	Systemic S/Sx (bilateral ptosis GI symptoms; visual, auditory, or other sensory disturbances; widespread hyperesthesia)	Moderate systemic bleeding (old scabs, gingival bleeding, epistaxis, etc.); bruising distant from the bite wound	Edema above elbow or knee but not beyond shoulder or hip; moderate local blistering along bitten limb segment
Severe	Difficulty speaking; altered mental status; respiratory muscle weakness causing difficulty breathing; shock or otherwise unstable patient	Active GI bleed (usually hematemesis) or other internal bleeding; severe anemia; altered mental status; shock or otherwise unstable patient	Progressive edema beyond shoulder or hip; severe necrosis or widespread blistering; symptomatic bite to head, neck, or torso; altered mental status; shock or otherwise unstable patient
Criteria for additional AV doses at hours 2, 4, 6, 12, 24 (as needed)	Additional dose if: persistence or worsening of systemic neurotoxic S/Sx. Continue to re-administer 2 vial boluses as needed at hours 2, 4, 6, 12, and 24 until signs of improvement begin to appear (↑SBC, ↑LOC, ↑strength, etc.)	Additional doses if: persistence, resumption, or new onset of any active external or internal bleeding **OR** S/Sx of active venom confirmed by secondary recurrence of abnormal WBCT	Additional doses if: significant increase in edema (such as beyond major joint) **OR** significant increase in pain (severity of pain and/or how far pain radiates up the bitten limb)
NORTHCOM **1st Line Antivenoms**	U.S: Coral snake envenomations Initial 3-5 vials NACSA, additional doses not needed if 5 vial initial dose given U.S./Canada: Pit viper envenomations* - CROFAB: Initial dose = 4-6 vials, additional doses = 4-6 vial as needed - ANAVIP (rattlesnakes only): Initial dose = 10 vials, - additional doses = 10 vials as needed *Follow unified treatment algorithm	U.S./Canada: Broad spectrum coverage all hemotoxic/cytotoxic syndromes* Any pit viper envenomation (rattlesnake, copperhead, cottonmouth): - CROFAB: Initial dose = 4-6 vials, additional doses = 4-6 vials as needed Rattlesnake envenomations only: - ANAVIP: Initial dose = 10 vials, additional doses = 10 vials as needed NOTE: Anavip is only indicated by FDA for rattlesnake envenomations; not for copperheads or cottonmouths at this time; however, it is likely effective against all North American pit vipers. Follow Unified treatment algorithm for the management of crotaline snakebite in the U.S. (Lavonas et al. 2011) for dosing and management guidelines on pit viper bites.

BTG Therapeutics, USA – CroFab

(Freeze-dried/Refrigerated) [94,95,101,249-250] :

- **Indications:** Envenomation by all Pit Viper species (rattlesnakes, copperheads, cottonmouths) in North America. Freeze-dried; requires refrigeration but one study has demonstrated that it will maintain efficacy under field conditions for ≥ 90 days if needed.
- **Initial dosing:** 4 – 6 vials

RDT/Instituto Bioclon, USA/Mexico – ANAVIP

(Freeze-dried/Unrefrigerated) [92]

- **Indications:** Currently only indicated by FDA for rattlesnake envenomations.
- **Not currently indicated for copperhead or cottonmouth envenomations**, although this may change in the near future depending on results of upcoming studies. Freeze dried and field-stable at room temperature of 25º C / 77º F.
- **Initial dosing:** 10 vials

Pfizer, USA – North American Coral Snake Antivenom (NACSA)

(Freeze-dried/Refrigerated) [251]

- **Indications:** Indicated for neurotoxic envenomations by North American coral snake (NACSA) species in the United States including Eastern coral snake *(Micrurus fulvius)* and Texas coral snake *(Micrurus tener)*. Store between 2 – 8º C / 35.6 - 46.4 ºF; however, likely retains stability for short excursions in the field.
- **Initial dosing:** 5 vials

SOUTHCOM

Treatment Guidelines

Safe and effective antivenoms are available for all hemo/cytotoxic pit viper envenomations and for neurotoxic coral snake envenomations in this AOR. Treatment does not require identification of the species responsible but does require identification of the syndrome. Snakebite treatment at the point of injury is recommended for SOUTHCOM. This section provides specifics about antivenoms use in this region.

Adverse Reaction Management

- If a mild or moderate reaction occurs, slow the infusion, and treat symptomatically with antihistamines, steroids, and/or antiemetics as needed.
- If a severe reaction such as anaphylaxis occurs, stop the infusion, and treat according to the anaphylaxis protocol listed elsewhere in the CPG. Reassess the patient once the reaction has been controlled and resume the infusion at a slower rate if any of the specific criteria for antivenom treatment listed elsewhere in the CPG have not completely resolved.

Sudden Collapse Syndrome Treatment Protocol

Patient presents within 30 minutes of the bite with rapid onset shock ± angioedema, altered mental status, systemic bleeding, and diarrhea.[1]

5. Stabilize with IM or IV epinephrine and fluids as per anaphylaxis protocols
6. Intubate for airway edema not rapidly responsive to epinephrine
7. Follow epinephrine immediately with a high dose of the appropriate regional antivenom given by rapid IV or IO push during the resuscitation
8. Maintain blood pressure with IV or IO fluids and epinephrine until antivenom has taken effect to reverse the hypotension.

See Sudden Collapse Syndrome section for more information.

Initial dose = 15 vials, additional 5 vials as needed

FIRST LINE (Entire SOUTHCOM AOR): BIOCL-AVT

Instituto Bioclon, Mexico – ANTIVIPMYN-TRI (BIOCL-AVT) (Freeze dried/Unrefrigerated) [251-255]:

1. Field-stable. Broad-spectrum coverage 14 species Hemo/Cyto.
2. First line treatment option for all hemotoxic and cytotoxic snake envenomations anywhere in the SOUTHCOM AOR when the causative species is either unknown or among the ≥ 14 snakes for which this product is directly indicated. Directly or indirectly covers most of the WHO category 1 and category 2 snakes in this region.
3. Initial dose = 10 vials hemotoxic/cytotoxic only, additional doses = 5 vials as needed.

Feasibility of use in austere environments: Recommended for operational settings. Unrefrigerated storage at ambient tropical temperatures of ≤ 37º C / 98.6º F. Lyophilized product that likely retains stability at higher temperatures for short excursions. Recommend carrying full dose or loading dose (≥ 5 vials) into field on extended operations in austere environments and storing larger quantities at strategically located Role 2 & 3 facilities in SOUTHCOM AOR.

Adverse reactions: High-quality product with low rates of reactions anticipated.

Indications: This broad-spectrum polyvalent can be used to treat hemotoxic and cytotoxic envenomations by more than 14 different species of Central and South American snakes. It may be able to neutralize venom from additional species through paraspecific neutralization, but this has not been officially determined. The species listed below are the official treatment indications recommended by the manufacturer:

- HEMOTOXIC and/or CYTOTOXIC: *Crotalus durissis terrificus; Bothrops asper, B. atrox, B. neuwiedii, B. alternatus, B. jararacussu, B. venezulensis, B. pictus, B. brazili; Lachesis muta muta, L. m. stenophyrs; Sistrurus spp.; Agkistrodon spp*.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met.

Initial dosing by syndrome:

- NOT INDICATED FOR NEUROTOXIC
- HEMOTOXIC initial dose = 10 vials
- CYTOTOXIC initial dose = 10 vials

Additional dosing: Additional doses of 5 vials BIOCL-AVT may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE (SOUTHCOM – Central America/South America): BIOCL-COR

SECOND LINE (SOUTHCOM – South America): BIOCL-COR

Instituto Bioclon, Mexico - CORALMYN (BIOCL-COR) (Liquid/Refrigerated) [256-262]:

1. Not field stable. Broad-spectrum coverage neuro in Central America.
2. First line treatment option for neurotoxic envenomation in Central America by coral snakes or unknown species (coral snakes are only strictly neurotoxic snakes in SOUTHCOM AOR). Second line treatment option for coral snake / unknown neurotoxic envenomation in South America if first line (INS-AAP) is not available.
3. Initial dose = 10 vials neurotoxic only, additional doses = 5 vials as needed.

First Line (SOUTHCOM – Central America): Neurotoxic envenomation in Central America by coral snakes or unknown species (coral snakes are only strictly neurotoxic snakes in SOUTHCOM AOR).

Second Line (SOUTHCOM – South America): May treat some coral snakes in South America but major coverage gaps in that region compared to the first line for South America (INS-AAP).

Feasibility of use in austere environments: Not recommended for operational settings. Requires cold chain refrigeration between 2 - 8 ºC (35.6 - 46.4 ºF). Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities in South America. Likely to retain efficacy for several weeks in the field but should be disposed of after that duration of time outside refrigeration.

Adverse reactions: High-quality product with low rates of reactions anticipated.

Indications: This polyvalent can be used to treat neurotoxic envenomations by most major species of Central American coral snakes from the genus *Micrurus*.

- NEUROTOXIC: Central American coral snakes (*Micrurus spp*.)

Initial dosing by syndrome:

- NEUROTOXIC syndrome initial dose = 10 vials
- NOT INDICATED FOR HEMOTOXIC ENVENOMATIONS
- NOT INDICATED FOR CYTOTOXIC ENVENOMATIONS

Additional dosing: Additional doses of 5 vials BIOCL-COR may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

FIRST LINE (SOUTHCOM – South America): INS-AAP

SECOND LINE (SOUTHCOM – Central America): INS-AAP

Instituto Nacional de Salud, Colombia - Antiveneno Anticoral Polivalente (INS-AAP) (Liquid/Refrigerated) [260-2]:

1. Not field stable. Broad-spectrum coverage Neuro in South America.
2. First line treatment option for neurotoxic envenomation in South America by coral snakes or unknown species (coral snakes are only strictly neurotoxic snakes in SOUTHCOM AOR). Second line treatment option for coral snake / unknown neurotoxic envenomation in Central America if first line (INS-AAP) is not available.
3. Initial dose = 10 vials neurotoxic only, additional doses = 5 vials as needed.

First Line (SOUTHCOM – South America): Broadest efficacy against neurotoxic snake bites by coral snakes or unknown species in South America. Coral snakes are the only strictly neurotoxic species in SOUTHCOM.

Second Line (SOUTHCOM – Central America): Should treat most coral snake species in Central America but will have some coverage gaps compared to the first line for Central America (BIOCL-COR).

Feasibility of use in austere environments: Not recommended for operational settings. Liquid product that requires cold chain refrigeration between 4 - 8 ºC / 39.2 - 46.4 ºF. Recommend storing several vials at a small number of strategically located Role 2 & 3 facilities in South America. Likely to retain efficacy for several weeks in the field but should be disposed of after that duration of time outside refrigeration.

Adverse reactions: High-quality product with low rates of reactions anticipated.

Indications: This polyvalent can be used to treat neurotoxic envenomations by most major species of South American coral snakes from the genus *Micrurus* as well as some Central American species.

- NEUROTOXIC: South American coral snakes (*Micrurus spp.)* including *Micrurus dumerilii, M. mipartitus, M. surinamensis, M. isozonus, M. lemniscatus, M. spixi, M. Medemi*

Initial dosing by syndrome:

- NEUROTOXIC syndrome initial dose = 10 vials
- NOT INDICATED FOR HEMOTOXIC ENVENOMATIONS
- NOT INDICATED FOR CYTOTOXIC ENVENOMATIONS

Additional dosing: Additional doses of 5 vials INS-AAP may be given at hours 2, 4, 6, 12, and 24 if needed.

Pretreatment: Not routinely indicated unless patient is unstable, asthmatic/atopic, known hypersensitivity or other pretreatment criteria met. Low risk of severe allergic reactions and other EARs.

Preparation and administration: Dilute the entire dose of antivenom in a single 250 - 500 mL bag of isotonic solution and administer by intravenous infusion over 10 - 30 minutes.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients injured by snakes.

INTENT (EXPECTED OUTCOMES)

1. All snakebite patients should be managed according to the steps outlined in the Universal Approach to Snakebite Assessment, Diagnosis, and Treatment section.
2. Assessment, diagnosis, and treatment of snakebite patients should be based on the clinical syndrome of envenomation and not the identity of the snake species responsible for the bite.

   When a broad-spectrum antivenom does not exist for a given syndrome in a given area, follow the steps outlined in the regional algorithms to determine the most appropriate antivenom therapy for the patient.
3. Snakebites are dynamic events and patients must be frequently reassessed for signs of neurotoxic, hemotoxic, and cytotoxic syndromes throughout the course of care as some syndromes will develop than others.
4. There are no absolute contraindications to antivenom administration for a patient with a symptomatic snake envenomation.
5. Antivenom administration should be performed by medical providers capable of providing advanced life support and trained to a minimum level of paramedic (or DoD equivalent) and higher (i.e. SOCM, 18D, PJ, IDC, IDMT, RN, PA, MD or DO, etc.)
6. Early antivenom treatment is the standard of care for snake envenomations worldwide. Whenever possible, the appropriate antivenom should be administered in the field prior to medevac to neutralize circulating venom before significant and potentially irreversible damage has occurred.
   - Field-stable, broad-spectrum antivenom options are included in this CPG for all combatant commands except for EUCOM.
   - Appropriate regional products listed in the CPG should be stocked in Role 2 and Role 3 medical facilities. Far-forward units with paramedic level providers should be equipped with field-stable, broad-spectrum antivenoms that can be stocked in the aid station and carried into the field for extended periods of times at high temperatures without loss of efficacy.
7. If antivenom is not available, the patient should be transferred to a facility that maintains a stock of the appropriate antivenom. Confirm that the receiving facility has the correct antivenom in stock prior to transfer. If the receiving facility does not have the correct product(s) in stock, then that facility should be bypassed for a facility that is stocking the appropriate products.
8. Antivenom dosage, preparation, and administration procedures for each product should be performed as detailed for each specific product.
9. Tetanus prophylaxis should be given prior to discharge when needed.
10. Fasciotomy is contraindicated for snakebite and all cases of suspected compartment syndrome should be managed with additional doses of antivenom and elevation ≥ 60 degrees to reduce oncotic pressure in the bitten limb.

11. Initiate a telemedicine consult with a qualified snakebite expert for any questions, concerns, or unusual manifestations that arise.
12. Do not attempt to kill or capture the snake for identification purposes as treatment is based on clinical findings. If a photo of the snake is available it can be sent to an expert for identification, but this should not delay antivenom treatment in a symptomatic patient with signs and symptoms of any envenomation syndrome.

PERFORMANCE/ADHERENCE METRICS

1. Administration of antivenom to any patients with clinical signs and symptoms of neurotoxic, hemotoxic, or cytotoxic envenomations
2. Early administration of appropriate antivenoms to symptomatic patients in the field
3. Rapid transfer of patients to a facility stocking the appropriate antivenom if not available on site
4. Antivenom administration should be performed by an advanced life support qualified provider trained to the paramedic level (or DoD equivalent) or higher
5. Tetanus prophylaxis as needed
6. Manage elevated intracompartmental pressures with antivenom and do not perform fasciotomies.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Chief, JTS Program Manager, and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: WHOLE BLOOD CLOTTING TEST

Whole Blood Clotting Test for Venom-Induced Consumptive Coagulopathies

The whole blood clotting test (WBCT) is a simple but critical bedside gross examination used in the assessment, diagnosis, and therapeutic monitoring of snakebite patients in the developing world and remote environments.[1-10] Refer to the diagram below regarding instructions for performing the test. At minutes 20 and 30, the tube is gently picked up and tilted 90 degrees; a stable solid clot retained within the tube is scored "Grade 0" and indicates normal coagulation. Abnormal results are scored "Grade 1" for a partial, semisolid clot that breaks apart and detaches from the glass tube shortly after it is turned or "Grade 2" for completely incoagulable liquid blood that pours out of the tube immediately. Attempting to score the test earlier than 20 minutes will not yield accurate results due to the consumptive mechanism of the coagulopathy. Using a healthy donor as a control is ideal to confirm questionable findings.

Continue WBCT testing throughout the course of care to monitor for secondary resumption of venom-induced consumptive coagulopathy.[11-13] After control of the envenomation has been achieved, reassess WBCT every 24 hours throughout the course of hospitalization. It is important to remember that the WBCT must be interpreted in the context of the larger clinical picture. If a patient has improved in all parameters except for a persistent abnormal WBCT, it may reflect an inertia in replenishment of depleted clotting factors after a severe hemotoxic envenomation.[1] If the venom is active then hematocrit should continue to decrease or signs of ongoing hemolysis or bleeding should be present.

Whole Blood Clotting Test (WBCT)

Draw 2 mL of venous blood and transfer directly into a clean and dry glass tube. Leave it upright, open, undisturbed for 20 and/or 30 minutes at room temp.

Collection: a blood sample for WBCT testing immediately after collection.

After exactly 20 minutes, pick up the tube and invert it. If a solid clot is retained, the test indicates normal coagulation.

Normal: a solid clot is retaining upon inversion of the tube at 20 or 30 minutes (Grade 0, no coagulopathy).

If clot breaks down quickly upon inversion of the tube or fails to coagulate, the test indicates a coagulopathy.

Abnormal: clot degrades rapidly (Grade 1, friable clot) or fails to coagulate whatsoever (Grade 2).

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Global Spider and Scorpion Envenomation Management (CPG ID: 84)

This CPG provides an overview of spider and scorpion envenomation and presents a standardized approach to providers in the evaluation and treatment of patients with spider or scorpion induced poisoning.

BACKGROUND

Spider and scorpion envenomations can occur in many environments in which the military operates.[1] While most spider and scorpion envenomations result in mild symptoms, severe toxicity and death can occur.

Arthropods are a diverse group of animals with numerous species producing a wide array of toxins. Many arthropods possess a significant venom but lack a sufficient apparatus (fangs or talon) to inject it into humans. Most bites and stings involve more danger from anaphylaxis, but several species of spiders and scorpions have significant neurotoxic, cytotoxic, or hemotoxic venoms. Unfortunately, reliable data evaluating the impact of spider bites and scorpion stings on humans are lacking. Most knowledge is based on case reports and case series, frequently lacking expert review. Furthermore, the public frequently spreads inaccurate information (i.e. reporting a skin abscess resulting from *Staph. aureus* is a "spider bite").

Unlike other types of injuries, patients may not even recognize they were envenomated by arthropods, as many injuries are painless or felt as a pinprick. Anaphylaxis is the most concerning initial effect. Recognize and treat it immediately using standard acute allergic reaction therapies. Anaphylaxis from an arthropod envenomation is not an indication for antivenom. For all bites/stings, assess tetanus status and administer vaccine and/or immunoglobulin (for those not previously immunized against tetanus) if required. The following section describes the more clinically significant species of venomous arthropods, the toxicological syndrome they produce, and the treatment. Consider toxicology consultation using the ADvanced VIrtual Support for OpeRational Forces (AD.VI.S.O.R) line in any patient with systemic symptoms secondary to a spider or scorpion envenomation – Commercial: 1 (833)-ADVSRLN (238-7756) or DSN (312) 429-9089.

SPIDERS

While many spider species produce venom, the vast majority lack sufficiently large or strong enough fangs to penetrate human skin and cause clinically significant effects. However, spiders venomous to humans can be found throughout much of the world. Appendix A provides the geographical location of clinically significant venomous spider species.

WIDOW SPIDERS (*LATRODECTUS* SPECIES)

BACKGROUND

Multiple species of widow spiders (*Latrodectus spp.*) are found on various continents (North America, Asia, Europe, Africa, and Australia). They are generally black or brown with a red or yellow demarcation on their ventral and/or dorsal abdomen. A lack of a red or yellow demarcation on the spider does not exclude it from being a *Latrodectus spp*. They live in temperate and tropical latitudes and tend to inhabit shady enclosed spaces such as crevices, wood piles, and sheds. Humans are commonly bitten while in bed during the fall and early winter when the spiders are attempting to find warmth.

PATHOPHYSIOLOGY

Widow spider venom consists of multiple toxins which ultimately result in activation of the nervous system and muscle contraction.[2]

CLINICAL MANIFESTATION

Patients may or may not feel a pinprick upon the initial bite. A pair of small red spots at the envenomation site may be visible; however, the bite site is often not located.[3] Some patients do not develop systemic toxicity. In those patients who do, symptoms typically begin 15 to 60 minutes following the envenomation. The primary symptom is painful muscle cramping, starting at the bite site and progressing towards the center of the body. Patients may develop a painful, rigid abdomen secondary to abdominal muscle spasm which may be mistaken for peritonitis. The pain increases over time and may occur in waves. In some cases, the patient develops a temporary diaphoretic, grimaced, and contorted appearance of the face referred to as "*facies latrodectismica*."[4] Other symptoms include vomiting, diaphoresis, tachycardia, hypertension (often profound), and restlessness. Symptoms of *Latrodectus* envenomation last hours to days. Fatalities from *Latrodectus* envenomation are exceedingly rare and, when they do occur, are secondary to cardiac arrest (presumably from severe hypertension in patients with predisposing medical conditions) and wound infection.[5]

TREATMENT

Treatment consists primarily of supportive care, pain management, and wound care (to include tetanus prophylaxis). Given the low risk of infection, antibiotics are not routinely recommended.

Depending upon the severity of pain, acetaminophen, nonsteroidal anti-inflammatory agents, and opioids can be used for pain control. Benzodiazepines may improve muscle spasms.[6] Pain control and benzodiazepines are often sufficient to manage tachycardia and hypertension. In those patients with severe pain refractory to pain medications, antivenom (if available) may be indicated but may not be readily available.[7] Long term injury or death from *Latrodectus* is extremely unlikely. While rare, fatal allergic reactions to *Latrodectus* antivenom have occurred.[8] Fatal cases due to antivenom anaphylaxis have been reported in patients with asthma. Therefore, *Latrodectus* antivenom is not indicated in patients with otherwise manageable symptoms, particularly those that may be at higher risk (i.e. history of asthma). If administered, patients should be monitored for 4 hours, but prophylactic treatment for allergic reaction is not recommended. When patients do have significant symptoms meeting indications for antivenom, the antivenom is rapidly effective and curative. When necessary, expired vials of antivenom may be used.[9] The dose consists of one 2.5 milliliter vial of antivenom dissolved in one 2.5 milliliter vial of sterile water (provided in the antivenom kit) administered intravenously. While the package instructions permit intramuscular injection, this route is unlikely to provide sufficient absorption to manage symptoms.[10] While one dose is usually sufficient, a second dose may be administered if symptoms are not adequately controlled 15-30 minutes after the first dose.

In the event that medical personnel are unable to control the patient's symptoms with available pain medications and benzodiazepines, then medical evacuation is recommended.

VIOLIN SPIDERS (*LOXOSCELES* SPECIES)

BACKGROUND

Loxosceles reclusa in a venomous spider more commonly known as the brown recluse, violin spider, or fiddleback spider. As indicated by the common names, the spider has a brown shape/mark resembling a violin or fiddle on the dorsum of its cephalothorax. The *Loxosceles* genus has a worldwide distribution. The spiders prefer dark areas such as wood piles, crevices between rocks, and basements. While not aggressive, they will bite if antagonized.[11]

PATHOPHYSIOLOGY

Loxosceles venom is cytotoxic (toxic to living cells) and consists of two main constituents: sphingomyelinase-D and hyaluronidase. Hyaluronidase facilitates the spreading of the venom into tissue while sphingomyelinase-D causes necrosis and hemolysis. Sphingomyelinase also triggers an inflammatory reaction in red blood cells resulting in vessel thrombosis, tissue ischemia, and necrosis.[12]

CLINICAL MANIFESTATIONS

Loxoscelism will present as an ulcerative lesion, sometimes not until days after the initial envenomation. In general, within several hours after the initial bite there will be local ischemia resulting in pain, pruritus and swelling. A blister or a central area of purple discoloration will form. The venom causes vasoconstriction and can result in a pale border around the central ulcer/blister/discoloration. Over the next several days the ulcer enlarges and the borders demarcate until 1-2 weeks after the initial bite.[13]

In some cases, systemic loxoscelism can occur. The extent of the cutaneous reaction does not predict the development of systemic loxoscelism, which typically occurs 24 to 72 hours after the envenomation. Young pediatric patients are at greatest risk of reaction. Systemic loxoscelism manifestations include fever, weakness, vomiting, joint pain, petechiae, rhabdomyolysis, disseminated intravascular coagulation, and hemolysis. While rare, severe cases can result in hemoglobinemia, hemoglobinuria, kidney failure, and death.[14]

TREATMENT

Laboratory testing is not indicated for non-necrotizing local symptoms. Treatment of local symptoms includes wound care, tetanus prophylaxis, analgesics, and antipruritics as necessary. There is no antivenom available. Early excision, intralesional injection of corticosteroids, and dapsone are not indicated. The wound may be confused with a localized abscess, and diagnosis may be made following ineffective incision and drainage or antibiotic treatment. Corrective surgery can be performed after the wound has completed progression and has begun to heal, typically several weeks after the envenomation. Prophylactic antibiotics are not indicated, but should be used as appropriate if a secondary bacterial infection develops.[15]

Patients with an expanding necrotic lesion or symptoms of systemic loxoscelism should be admitted to a medical facility. A complete blood cell count, urinalysis for blood, metabolic panel, liver function and coagulation studies should be performed. In those patients who develop hemoglobinuria, increased IV fluid hydration can be used to attempt to prevent acute renal failure. Treat significant hemolysis with transfusions, including exchange transfusion in infants and young children with severe systemic loxoscelism.[16]

TARANTULAS

BACKGROUND/CLINICAL MANIFESTATIONS

There are more than 1500 species of tarantulas found throughout tropical and subtropical areas of the world. While tarantulas are often feared due to their large size and painful bite, their bite is not dangerous to humans. Some indigenous American tarantula species have barbed hairs with which they can strike their victims or they can generate a cloud of hairs (as a defense mechanism) by scratching their abdomen with their legs. These hairs can cause irritation and pruritus of the skin, eyes, and respiratory tract.[17]

TREATMENT

Tarantula bite treatment is supportive and includes cool compresses, analgesics, antipruritics, and tetanus prophylaxis as indicated. Adhesive tape can be used to remove barbed hairs from the skin. If hairs get in the eye, then irrigate copiously. If irrigation is ineffective, then removal by an ophthalmologic surgeon may be necessary. Skin irritation can be treated with topical and oral antihistamines and corticosteroids.[17]

FUNNEL WEB SPIDERS (*ATRAX*)

BACKGROUND

Australian funnel web spiders are capable of inducing a severe and potentially fatal neurotoxic envenomation syndrome. Unlike other species of the spiders, funnel web spiders can bite tenaciously and may have to be physically removed from the victim. They prefer to live on the ground in moist, temperate environments such as burrows, crevices between rocks, and near the foundations of homes. They are named for the tubular or funnel-shaped web they build.[18]

PATHOPHYSIOLOGY

The lethal component of funnel web spider venom is robustotoxin. It induces an autonomic storm by causing excessive release of acetylcholine, norepinephrine, and epinephrine.[19,20]

CLINICAL MANIFESTATIONS

Funnel web spider envenomation causes a biphasic envenomation syndrome. The first phase includes pain at the bite site, perioral tingling, piloerection, and regional fasciculations which may progress to muscle spasm. This muscle spasm may involve the face, tongue, and larynx leading to airway compromise. The increased stimulation of cholinergic and adrenergic systems causes nausea, vomiting, lacrimation, salivation, tachycardia, hypertension, cardiac dysrhythmias, and acute lung injury. Acute lung injury is the predominate cause of death during the first phase.[20]

In the second phase the symptoms of the first phase resolve and lead to the gradual onset of refractory hypotension, apnea, and cardiac arrest.[20]

TREATMENT

Prehospital management consists of pressure immobilization using an elastic crepe bandage applied tightly enough to limit lymphatic spread, but not to restrict blood flow. The venom of the funnel web spider is one of the few animal venoms to undergo local inactivation. The patient should be transported to the nearest medical facility with the bandage in place, and the bandage should not be removed until antivenom is readily available to be administered.[21]

An effective funnel web spider antivenom is available in Australia. An initial dose of 2 vials is indicated for patients with signs of envenomation, while a dose of 4 vials is indicated for pulmonary edema or decreased mental status. The initial dose is repeated every 15 minutes until the patient clinically improves. A dose of 8 vials is commonly reported in cases of severe envenomation.[21]

SCORPIONS

BACKGROUND

Scorpions envenomate humans by stinging them with the telson on their tail. The majority of medically significant envenomations occur in the Middle East, tropics (e.g., Southwest Asia, India, Central and South America), and North Africa. Scorpions are nocturnal, hibernate in the winter, and are active in the warm seasons. Humans are frequently envenomated by scorpions hiding in dark, hidden locations such as inside shoes and small crevices.

Given many scorpion envenomations occur in developing nations lacking significant medical infrastructure, data regarding scorpion envenomations and antivenoms are limited. Studies have estimated over 1.2 million scorpion envenomations per year globally with an overall fatality rate ranging from 0.27% to 0.52%.[22,23] The majority of severe and fatal envenomations occur in children under the age of ten due to their decreased body mass.

PATHOPHYSIOLOGY

Scorpion venoms are complex and can include phospholipase, acetylcholinesterase, hyaluronidase, serotonin, and neurotoxins. Scorpion venom increases neuronal release by blocking inactivation of the sodium channel, resulting in an increase in the amplitude and duration of neuron action potential. The overall result is excess stimulation of the central nervous system, the neuromuscular system, the sympathetic nervous system, and the parasympathetic nervous system.[24]

The components of scorpion venom are species specific and generally fall into the categories of neurotoxic and cardiotoxic; however, this terminology is misleading since the cardiotoxic effects are secondary to an excess release of catecholamines stimulated by the nervous system.[25]

The venom of one unique species of scorpion, *Hemicorpius lepturus*, found in Iraq and Iran is predominately cytotoxic, similar to the brown recluse spider.[26]

CLINICAL MANIFESTATIONS

Scorpion stings produce a painful local reaction often including the sensation of tingling or burning. Erythema at the injection site is common, and discoloration and necrosis sometimes occur.

Symptoms of excess sympathetic nervous system stimulation predominate over symptoms of parasympathetic nervous system stimulation. Sympathetic stimulation via excess catecholamine release produces hypertension, tachycardia, irritability, and agitation. In severe cases, patients may develop seizures and hyperthermia. Excess cardiovascular stimulation may result in myocardial ischemia, myocardial infarction, and cardiac dysrhythmia. In rare cases, severe outcomes occur like bradycardia and hypotension due to excess parasympathetic stimulation, or cardiovascular collapse resulting from catecholamine depletion.[27]

Clinical manifestations of the parasympathetic stimulation include salivation, nausea, vomiting, abdominal pain, pancreatitis, and priapism.[27]

Neuromuscular symptoms include tongue fasciculations, muscle spasms, dysphagia, and dysphonia. Roving eye movements is a classic finding of severe centruroides envenomation (the only clinically significant venomous scorpion indigenous to the United States). While infrequent, severe muscle spasm can result in airway compromise and respiratory arrest.[24]

Pulmonary edema commonly occurs in severe and fatal cases.[25] The pulmonary edema is both cardiogenic and non-cardiogenic in nature. The cardiogenic component is due to reduced cardiac output resulting from excessive sympathetic stimulation. The non-cardiogenic component is due to increased vascular permeability and release of vasoactive substances.

Hemiscorpius lepturus envenomations can cause local skin necrosis and in severe cases hemolysis, disseminated intravascular coagulation, and renal failure.[28]

TREATMENT

The diagnosis of scorpion envenomation is made clinically based on history, symptoms, and signs of envenomation. While older children and adults will almost universally report the initial painful sting, in nonverbal children the diagnosis may be more challenging. Laboratory analysis may reveal an elevated white blood cell count, serum glucose, lactate dehydrogenase, and amylase; however, these tests lack sufficient sensitivity or specificity to be clinically relevant. In those patients with moderate to severe symptoms, an electrocardiogram should be performed to evaluate for evidence of cardiac ischemia or dysrhythmias. A serum troponin may be measured to evaluate for cardiac ischemia.[29] If the envenomation occurred in Iraq or Iran and *Hemiscorpius lepturus* envenomation is suspected, a platelet count, prothrombin time, D-dimer, and fibrinogen level, blood urea nitrogen, and creatinine can be performed to evaluate for evidence of disseminated intravascular coagulation or renal failure.[30]

The majority of scorpion envenomations can be adequately managed with pain medications (ibuprofen, acetaminophen, and opioids) and routine wound management to include tetanus prophylaxis. Most patients, especially adults, will not develop significant symptoms. Patients should be observed for 4-6 hours after envenomation to ensure no delayed onset of symptoms. Prophylactic antibiotics are not indicated. Application of a tourniquet, cauterization, and incision and drainage are contraindicated in scorpion stings. Benzodiazepines may be used to treat significant agitation (which may cause hypertension) or seizures. Pharmacologic management of hypertension is generally not indicated. Intravenous vasopressors such as nitroprusside, nitroglycerin, labetalol, and phentolamine should be used in patients with severe or symptomatic hypertension refractory to benzodiazepines.[31]

For clinically significant envenomation, management is supportive and focused on the patient's symptoms. Benzodiazepines are the first line therapy for sympathomimetic toxicity.[31] Note that benzodiazepines under dosing for sympathomimetic toxicity and seizures is not uncommon. Administer Benzodiazepines aggressively to ensure symptom control. Intravenous propofol or phenobarbital in combination with endotracheal intubation may be used in severe cases. Other anticonvulsants such as phenytoin, levetiracetam, and valproic acid are generally not indicated since they do not treat the underlying sympathomimetic or anticholinergic toxidrome causing the seizures. Direct acting vasopressors (epinephrine and norepinephrine) are recommended to treat bradycardia and hypotension.

In patients with significant neuromuscular spasm, oral secretions, sedation, or other threats to the patent airway, perform endotracheal intubation to prevent aspiration and ensure adequate ventilation. Pulmonary edema should be managed with noninvasive or invasive ventilation in combination with optimization of cardiac output.[31]

The incidence of long-term sequelae resulting from scorpion envenomation is unknown; however, due to the potentially significant risk, priapism should be managed aggressively with antivenom (if available) and other standard treatments of priapism (aspiration and intracavernous injection of phenylephrine) with urology consultation.[32]

Antivenom is available for some species; data regarding the benefits and risks of many of these antivenoms are significantly limited. In patients with moderate to severe symptoms refractory to analgesics and

benzodiazepines, antivenom, if available, may be indicated. Due to the high risk of immediate or delayed allergic reactions to these antivenoms, intravenous histamine antagonists (i.e. diphenhydramine), steroids, and epinephrine should be immediately available at the patient's bedside prior to antivenom administration.

Appendix B provides scorpion sting clinical grading and treatment guidelines. Appendix C provides a list of scorpion antivenoms available by country and their dosing regimens. Several studies demonstrate improved efficacy of intravenous compared to intramuscular antivenom administration.[33] Antivenom dosing does not depend on patient weight or size and is the same for adult and pediatric patients.[34]

ADVERSE REACTIONS TO ANTIVENOM

Antivenoms have the potential to cause immediate and potentially life-threating, anaphylactoid reactions. Reactions can range from mild (pruritus, rash) to severe (wheezing, hypotension, respiratory distress, cardiovascular collapse, and death). Antivenoms may also cause serum sickness. Serum sickness is a type III hypersensitivity reaction which is characterized by flu-like symptoms with or without a rash that typically occurs between 2 days and 3 weeks after antivenom administration. Serum sickness is uncomfortable but not life threatening.[35]

ADVERSE REACTION MANAGEMENT

Unfortunately, data on the incidence of adverse reactions to antivenoms used outside of developed nations are lacking. Medical providers should anticipate a high likelihood for serious and potentially life-threatening anaphylactoid reactions to antivenoms not approved by the US Food and Drug Administration (FDA). For this reason, antivenom should only be used in patients with moderate to severe symptoms refractory to standard medical therapies (e.g., benzodiazepines and pain medications). Epinephrine should be immediately available at the patient's bedside prior to the administration of antivenom to ensure rapid administration if necessary.

For mild to moderate symptoms occurring during antivenom infusion (e.g., nausea, vomiting, urticaria, pruritus, chills, fever), stop the infusion immediately and treat symptoms with antiemetics, antihistamines (typically diphenhydramine), and steroids (i.e. methylprednisolone, prednisone, prednisolone). If the reaction is controlled after treatment and the patient's condition still requires antivenom, restart the antivenom at a slower infusion rate.

For severe reactions (i.e. respiratory distress, hypotension), immediately stop the antivenom infusion and treat using a standard anaphylaxis protocol (diphenhydramine 50 mg [1 mg/kg in pediatric patients] IV, methylprednisolone 125 mg [2 mg/kg in pediatric patients] IV, and 0.3 mg [0.15 mg in pediatric patients] of 1:1000 epinephrine intramuscularly).[36-39] Consider adding an H2 antihistamine such as famotidine. If necessary, intubate for airway edema not rapidly responsive to epinephrine. If antivenom is considered necessary to prevent death or disability, the antivenom may be reinitiated at a slower rate of infusion in conjunction with an epinephrine infusion.

In patients who develop serum sickness, management consists of symptomatic treatment with antihistamines and pain medications with or without a course of oral steroids.[35]

PERFORMANCE IMPROVEMENT (PI) MONITORING

INTENT (EXPECTED OUTCOMES)

- Rapid evaluation and transfer to site with antivenom capability for envenomation
- Tetanus prophylaxis when appropriate

PERFORMANCE/ADHERENCE MEASURES

- Transfer of patients with moderate to severe symptoms (grades 3 and 4) to antivenom if not available at site
- Aggressive use of benzodiazepines as indicated for agitation, neuromuscular stimulation, tachycardia, and hypertension
- Tetanus prophylaxis for all bites and stings

DATA SOURCE

- Patient record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually. Additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief, JTS Program Manager and the JTS PI Branch.

RESPONSIBILITIES

It is the clinical team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

APPENDIX A: LOCATION OF CLINICALLY SIGNIFICANT VENOMOUS SPIDER SPECIES

Geographical Location of Clinically Significant Venomous Spider Species			
Continent	**Latrodectus (i.e. Black Widow)**	**Loxosceles (i.e. Brown Recluse)**	**Funnel Web**
Africa	X	X	
Asia	X	X	
Australia	X	X	X
Europe	X		
North America	X	X	
South America	X	X	

APPENDIX B: CLINICAL GRADE AND TREATMENT OF SCORPION STINGS

Clinical Grade and Treatment of Scorpion Stings		
Grade	**Effects**	**Treatment**
1	Local effects only	Analgesia, tetanus prophylaxis
2	Mild/Moderate autonomic excitation (i.e. tachycardia, hypertension)	Benzodiazepines, cautious use of beta-antagonists and vasodilators
	Agitation and anxiety	Benzodiazepines
	Pain and paresthesias remote from the sting site	Analgesia
3	Pulmonary edema	Antivenom, noninvasive or mechanical ventilation
	Hypotension and cardiogenic shock	Antivenom, vasopressors (i.e., norepinephrine, epinephrine)
	Neuromuscular excitation, somatic neuromuscular dysfunction **or** cranial nerve dysfunction (associated with *Centruroides* species)	Antivenom, benzodiazepines
4	Multiorgan failure, coma, seizures, end-organ damage secondary to hypotension, somatic neuromuscular dysfunction **and** cranial nerve dysfunction (associated with *Centruroides* species)	Antivenom, vasopressors, sedation (benzodiazepine, propofol, phenobarbital), mechanical ventilation

Modified from Isbister and Bawaskar.[39]

APPENDIX C: SCORPION ANTIVENOMS AVAILABLE IN EACH COUNTRY

Antivenoms Available in Each Country			
Country	**Species the antivenom treats**	**Antivenom**	**Antivenom dosing regimen**
Morocco	*Androctonus australis garzonii, B. occitanus tunetanus, Tityus serrulatus*	Polyvalent scorpion antivenom	2-10 mL IV
Egypt	*Leiurus quinquestraitus, Androctonus amoreuxi, Androctonus crassicauda, Androctonus aeneas, Androctonus australis, Scorpio marus palmatus, Buthus occitanus*	Purified polyvalent anti-scorpion serum (equine)	5 1-mL ampules IV
Algeria	*Androctonus australis*	Scorpion antivenom (Pasteur Institute of Algeria)	10 mL IV Note: one study showed no benefit with this dose.
Mexico, United States	*Centruroides limpidus, C. noxius, C. suffuses, C. exilicauda*	Polyvalent scorpion antivenom	3 vials, each reconstituted in 5 mL of sterile normal saline (NS). Combine all 3 reconstituted vials in 50 mL NS infused IV over 10 minutes
Brazil	*Tityus serrulatus*	Soro antiescorpionico	20 mL IV
South Africa	*Parabuthus spp.*	Monovalent scorpion antivenom	5-10 mL IV
India	*Hottentotta/Mesobuthus tamulus*	Monovalent red scorpion antivenom	2-8 vials, each diluted into 10 mL of distilled water and administered IV over 5-7 minutes
Tunisia	*A. australis, B. occitanus*	Bivalent scorpion antivenom (Institut Pasteur, Tunis, Tunisia)	20 mL IV; however, one study showed no benefit
Saudi Arabia	*Leiurus quinquestriatus, Androctonus crassicauda, Buthus arenicola, Buthus mimax, Buthus occitanus, Leiurus quinquestriatus hebreus, A. amoreuxi*	Polyvalent scorpion antivenom	Manufacturer recommends 1 ampule, repeated until symptoms controlled. One study found a typical effective dose to be 5 to 20 1-mL ampules IV
Israel	*Leiurus quinquestriatus*	Monovalent scorpion antivenom	5 to 15 mL of antivenom diluted in 5% dextrose and 33% sodium chloride administered IV
Argentina	*Tityus trivittatus*	Scorpion antivenom	See package instructions.
Venezuela	*Tityus zulianus*	Scorpion antivenom	See package instructions.

Modified from Bahloul et al.[25]

APPENDIX D: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including an appropriate information sheet for distribution to patients within an appendix, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

High Bilateral Amputations and Dismounted Complex Blast Injury (CPG ID: 22)

To review indications for and the procedures associated with the initial management of bilateral lower extremity amputations with associated pelvic/perineal injuries.

Appendix A: Additional Information Regarding Off-label Uses in CPGs 10

BACKGROUND

The Dismounted Complex Blast Injury (DCBI) injury pattern consists of (generally proximal) bilateral lower extremity amputations with associated pelvic/perineal injuries and frequently also includes upper extremity injuries (which may be bilateral but most commonly involve the left side due to weapon carrying stance at the time of injury) as well as frequent thoracoabdominal or neuraxial injuries. DCBIs represent one of the most challenging cohorts of surgical patients from management of the initial injury through definitive reconstruction. These injuries are associated with a high incidence of both morbidity and mortality. Survival is initially dependent upon hemorrhage control and massive transfusion and resuscitation protocols. A coordinated team approach is essential to provide simultaneous airway management, volume resuscitation (ideally with Whole Blood (WB) or ratio transfusion), and immediate control of life threatening hemorrhage.[1]

Later risks for mortality include sepsis and multisystem organ dysfunction. These injuries can broadly be divided into two categories; those with a perineal/pelvic floor injury and those without. Counterparts or similar injuries in civilian trauma remain rare. An organized aggressive continuum of care from the Point of Injury (POI) onwards by medics, anesthetists, general and orthopaedic surgeons and intensivists is critical to optimize outcomes.

EVALUATION AND TREATMENT

INITIAL RESUSCITATION

These patients typically arrive in extremis shortly after injury. Tourniquets are often in place on all injured extremities. Due to profound shock and associated upper extremity amputations, IV access may not be obtained in the field. Rapid placement of Intra-Osseous (IO) lines is sometimes a useful adjunct to begin resuscitation prior to venous access. Large bore central venous access should be considered early and placed by an experienced proceduralist. This injury pattern mandates immediate activation of massive transfusion protocols, the preferential use of fresh packed red blood cells (< 21 days old), minimal use of crystalloid products, and early consideration for the use of WB, if blood resources are limited. Refer to the Damage Control Resuscitation (DCR) and WB Transfusion CPG for specific recommendations.[2,3]

ROLE OF RESUSCITATIVE THORACOTOMY

Occasionally these patients arrive with CPR in progress. When signs of life are present, consideration of resuscitative thoracotomy should be given according to established CPGs. Outcome data from OIF suggest a reasonable survival rate in properly selected patients.[4,5] Another alternative described with exsanguination in civilian extremity injuries is the use of a brief period of CPR with concomitant massive blood product resuscitation before resorting to a resuscitative thoracotomy. A review of the Department of Defense Trauma Registry (DoDTR) in 2011, suggests the mortality associated with bilateral high amputations, pelvic injury and emergency department thoracotomy is very high (>90%). Experienced military surgeons debate the optimal approach to prevent ongoing hemorrhage in this population – thoracic, distal aortic or bilateral iliac proximal vascular control. Endovascular aortic balloon occlusion may offer an elegant alternative for proximal vascular control in the future.[6]

TRIAGE CONSIDERATIONS

These patients can consume massive amounts of blood products and utilize multiple surgical assets to include operative teams, equipment and operative hours. In multiple casualty scenarios, a prudent assessment of resource allocation should be done prior to proceeding with resuscitative thoracotomy.

PREOPERATIVE STUDIES

Useful preoperative studies may include chest radiograph, anterior-posterior pelvic radiograph, Point-of-Care Ultrasound and Diagnostic Peritoneal Lavage, but should not delay surgical control of hemorrhage. Expeditious computed tomography of the head may be considered in patients displaying lateralizing signs consistent with severe traumatic brain injury requiring operative intervention, but should not degrade resuscitation or delay surgical hemorrhage control.

OPERATIVE APPROACH

PRIORITIZATION AND SURGICAL TEAMS

The initial operative goal is hemorrhage control and control of contamination. Due to the nature of these injuries, this is best achieved using a team of general and orthopaedic surgeons working concurrently on the patient, when possible. For example, two surgeons can achieve proximal control and address intra-abdominal injuries while a second team focuses on the amputations. A third team can be utilized to address upper extremity injuries, if present. This approach maximizes efficiency and limits prolonged physiologic insult to a severely injured patient. Prior to operation, the most critical procedures (e.g. proximal hemorrhage control, control of contamination, completion amputations, bladder repair and potential colonic diversion) should be listed, keeping in mind reasonable parameters to terminate surgery.

PROXIMAL VASCULAR CONTROL

The level of proximal vascular control is dictated by several clinical variables: previous resuscitative thoracotomy, associated pelvic disruption, level of tourniquet placement and level of amputation(s). Typically vascular control should be achieved at the most distal level possible, including control via a retroperitoneal approach or in the groin. A strategy of walking the clamps down in patients with massive pelvic injuries is prudent. This involves laparotomy, infra-renal aortic control, and movement of control distal to the internal and external iliacs.[7] In the case of pelvic floor injuries with open pelvic wounds and active posterior bleeding, temporary control of the internal iliacs is prudent. This can be achieved with vascular clamps, vessel loops, Rummel tourniquets, or vascular clips. The benefit of achieving hemorrhage control must be balanced against the risk of ischemic tissue at the site of injury and subsequent infection and diminished wound healing. An attempt to reperfuse the internal iliacs should be made at the index or subsequent procedure. Ligation of both internal iliac arteries is to be avoided if at all possible; in cases of ongoing pelvic hemorrhage despite pelvic packing and angiographic embolization if available, bilateral internal artery ligation may be necessary although significant tissue necrosis (e.g., buttocks) can be anticipated.

ROLE OF PROXIMAL DIVERSION

In patients with an obvious need to divert the fecal stream due to pelvic disruption or an open pelvic fracture, stapled interruption of the sigmoid colon at the pelvic brim should be performed early to facilitate pelvic exposure and vascular control. Formal colostomy should be delayed until subsequent operative procedures when the patient is more stable.

ORTHOPEDIC CONSIDERATIONS

It is common for these patients to present with traumatic bilateral lower extremity amputations at various levels from transtibial amputations to very high transfemoral amputation's, often with extremely complex soft tissue blast wounds up to and including the perineal and gluteal region. (See Figure 1 on next page.) Associated traumatic amputation of the non-dominant upper extremity is also common. The most challenging cases involve open pelvic ring and peri-acetabular fractures (Figure 2 next page) and dislocations associated with severe perineal injuries. Initial orthopaedic resuscitative involvement entails assuring that extremity hemorrhage control is sufficient with tourniquets. After the initiation of volume resuscitation, patients can often bleed

through in-place field tourniquets; in this case, they require placement of additional field tourniquets or pneumatic ones (if available) to control bleeding until optimized in the operating theater. Quick examination of the pelvic ring should be performed to address stability. Pelvic fractures can be stabilized with the use of clamped sheets or commercial pelvic binders centered over the trochanters.

Figure 1. Dismounted Complex Blast Injuries

Figure 2. Open Pelvic Ring and Acetabular Fractures

Figure 3. Same Patient After Pelvic External Fixation

Index operative procedures should be prioritized with surgical team leader.[8] Hemorrhage control of traumatic amputated limbs and peri-pelvic sources is the priority. Pelvic and perineal packing is helpful for tiny vessel hemorrhage control and cases with continued oozing due to coagulopathies. In the multilevel amputee, limb length is inversely proportional to later energy expenditure. Revision or completion amputations should occur at the most distal viable level with double ligation of all named vessels in an open, length-preserving fashion. Atypical rotational flaps are greatly preferred over guillotine-style or open circular amputations. Care should be given to salvaging healthy tissue for flap coverage, even if it is an atypical rotational flap in the face of destroyed or missing conventional flap tissue. When necessary, maintained pelvic ring stabilization with external fixation (Figure 3 above) is preferable to prolonged use of binders due to proximity of wounds and serial debridements that will be required. Anterior superior iliac spine/iliac crest or anterior inferior iliac spine pins are both appropriate, with the latter offering the greatest reduction control but requires available fluoroscopy and surgeon experience. Consideration should be given for later reconstructive orthopaedic pelvic incisions so as to appropriately divert the location of colonic and urinary streams. External fixation of long bone fractures should be accomplished during the index procedure, when possible. Smaller bone and joint fractures can be addressed if the patient remains stable, otherwise they are cared for after the initial operative resuscitation, such as splinting in the intensive care unit or during subsequent surgical procedures.

SOFT TISSUE DEBRIDEMENT

(See Management of War Wounds CPG[5])

Adequate initial surgical debridement is critically important. DCBI wounds are typically complex and extensive. They may be grossly contaminated with dirt, fragment debris, clothing and foliage. Wounds should be incised with well-planned incisions extending from the primary zone of injury to healthy tissue. Systematic debridement of nonviable skin, subcutaneous tissue, fascia, muscle, periosteum and bone is critical to reduce the bioburden and later risk of sepsis.[9,10] Blast wounds tend to evolve; if tissue is questionable and not contaminated it should be maintained and addressed at later surgical interventions. However, since the timing of the next operation (often at the next echelon of care) is unpredictable, avoid leaving marginally viable tissue behind as many of these complex wounds will develop progressive necrosis. When present, pelvic/perineal and pelvic wounds need to be similarly addressed.

ASSOCIATED VASCULAR INJURIES

DCBI injury pattern appears to be associated with iliac vein injury. When possible these injuries should be shunted or repaired rather than ligated. Unless easily repairable, arterial injuries in these critically injured patients should be managed initially with shunting followed by formal repair at subsequent operation. Care should be taken to avoid exclusion of the profunda femoris during shunting or repair, in order to perfuse the soft tissue and muscle.[11]

ASSOCIATED GU INJURIES

Associated injuries to the ureters, urethra, bladder, scrotum, penis, and prostate are common. These should be addressed if feasible with a focus on hemorrhage control, urinary control or diversion, and preservation of tissue for later reconstruction. See *JTS Urologic Trauma Management* CPG for specific recommendations.[9]

ASSOCIATED (OCCULT) RECTAL INJURIES

Computerized Tomography (CT) alone may not always accurately exclude penetrating distal rectal injury in the setting of multiple perineal or perirectal fragmentation wounds with scatter artifact and random trajectories. Therefore, fragmentation wounds to the perineum and perianal regions should generally prompt proctoscopic examination of the rectum even if digital rectal examination in the emergency room is negative for blood. This may be difficult in the supine position and may be readily completed in the supported lateral position. Completion of the proctoscopic exam should be done prior to completing laparotomy as colonic diversion may be indicated even if there is no other strict indication based on the proximity of blast wounds to the fecal

stream. If clot or active bleeding is identified on proctoscopic examination, the distal sigmoid colon/proximal rectum should be divided and later matured at a subsequent operation into an end colostomy once the patient is stabilized further along the evacuation chain.

Distal rectal wash out is not always necessary unless there is bulky retained stool in the presence of a suspected penetrating injury.

CONSIDERATION OF PRONE POSITIONING

In most patients, the posterior soft tissue injuries can be addressed with elevation of the amputated stumps or with the patient in a lateral position after the supine portion of the case has been completed. However, certain injury patterns have a large posterior element. In these cases it is sometimes necessary to prone the patient during the index procedure after hemorrhage control, for debridement of deep blast wounds in the gluteal and low back region. This decision should not be made lightly due to the time requirements and risks involved and can often be deferred to secondary procedures. When undertaken, the use of a Jackson table can facilitate a safe transition to the prone position. Unstable pelvic ring injuries should be stabilized prior to proning a patient as this position can exacerbate pelvic volume widening and resulting hemorrhage. Alternatively, lateral positioning with a bean bag may be considered.

TEMPORARY ABDOMINAL CLOSURE

Liberal use of temporary abdominal closure with delayed stoma maturation is advised.

WOUND DRESSINGS

Traumatic wounds should not be definitively closed until multiple adequate debridements have been performed and serial wound stability and maturation demonstrated. By nature, the extensive soft tissue destruction and degree of contamination in these wounds make them infected until proven otherwise, and a series of surgical debridements is necessary to prepare wounds for closure or coverage. If necessary and in the face of clean viable tissue, incisions made to extend the zone of wounds to healthy levels can be loosely approximated to prevent massive skin retraction. The preferred initial wound dressings include moist-to-dry, Dakin's soaked gauze, antibiotic bead pouches or negative pressure wound therapy with reticulated open cell foam or moist gauze.

PERIOPERATIVE MANAGEMENT

NEED FOR RADIOLOGIC IMAGING

These injuries are associated with a significant transfer of energy to the casualty, resulting in high risk for associated injuries of a blunt and penetrating nature. Once the patient is physiologically stabilized, complete imaging including "Pan Scan" CT and plain film examination should be obtained to evaluate for occult injury.[2]

NEED FOR REPEATED DEBRIDEMENTS

The treatment team must appreciate the phenomenon of wound evolution and the high risk for invasive fungal infection and expect that viability of the soft tissues will fluctuate over the course of several days. In the acute phase (<72 hours from injury) wounds should be frequently inspected in the operation room (e.g. every 24 hours). In the later, sub-acute phase (3-7 days from injury) wounds may require less frequent treatment based on the presence of viable tissue and absence of ongoing necrosis or persistent contamination. Multiple debridements are routinely required and the massively injured, physiologically deranged patient should not undergo excessive surgical procedures during the initial operation other than those required to control hemorrhage and gross contamination. See the JTS *Initial Management of War Wounds* and *Invasive Fungal Infection* CPGs on the JTS CPG website for further guidance.[10,12]

ROLE OF SYSTEMIC AND TOPICAL ANTIBIOTICS

Initial antibiotic selection should avoid empiric broad spectrum coverage but rather focus on narrow spectrum antibiotics, such as first generation cephalosporins, and the liberal use of topical delivery with Dakin's soaked gauze or antibiotic beads. See *JTS Infection Prevention in Combat-Related Injuries CPG* for specific recommendations.[13]

ROLE OF VTE PROPHYLAXIS

DCBI patients are at very high risk of developing proximal deep vein thrombosis (DVT) and associated pulmonary embolus (PE). The presence of lower extremity amputation does NOT reduce this risk. In fact, patients with lower extremity amputations may actually be at higher risk for development of DVT and PE than those with similar injury severity without lower extremity traumatic amputation. It is recommended that these patients be started on appropriate DVT/PE prophylaxis as soon as coagulopathy is reversed. If contraindications to prophylactic anticoagulation persist, prophylactic IVC filter placement should be strongly considered. See *JTS Prevention of Venous Thromboembolism – Inferior Vena Filter CPG* for further recommendations.[14]

TRANSFER OF CARE

The down-range surgeons should make every effort to coordinate dressing changes and necessary repeat debridements in anticipation of required patient transport up-range. Given the propensity for wounds to evolve in their acute phase, the down-range surgeons must maintain a low threshold to perform additional debridement prior to evacuating the casualty if the patient would otherwise require an unacceptable interval between debridements. Given the unpredictable nature of the air evacuation system and to optimize timing of subsequent serial debridements, the patient should remain NPO for flight so that they are prepared for the next operation.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All combat casualties with bilateral lower extremity amputations, at least one above the knee, with mechanism of injury explosive/IED or landmine, dismounted.

INTENT (EXPECTED OUTCOMES)

1. The pelvis is stabilized prehospital or immediately on arrival to the hospital with pelvic binder or junctional tourniquet placement in all patients with bilateral lower extremity amputations.
2. All patients who undergo laparotomy have temporary abdominal closure at first operation (or reason to safely close abdomen is documented).
3. All patients with high bilateral lower extremity injuries have a documented rectal exam, and have a documented proctoscopy if perineal/peri-rectal penetrating wounds are present.
4. When GU injury is present, debridement conserves tissue to the greatest extent possible.
5. All patients with dismounted complex blast injury have a second debridement performed within 24 hours of the initial debridement.
6. All patients have VTE prophylaxis started within 24 hours (or documented reason why contraindicated).

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients in the population of interest who have the pelvis stabilized prehospital or immediately on arrival to the hospital with pelvic binder or junctional tourniquet placement.

2. Number and percentage of patients in the population of interest who undergo laparotomy and the number who have temporary abdominal closure at first operation (or reason to safely close abdomen documented).

3. Number and percentage of patients in the population of interest who have documented rectal exam.

4. Number and percentage of patients in the population of interest who have perineal/peri-rectal penetrating wounds who have a documented proctoscopy.

5. Number and percentage of patients in the population of interest who have injury to external genitalia who have preservation of injured testicle(s) at the initial operation.

6. Number and percentage of patients in the population of interest who have a second debridement performed within 24 hours of the initial debridement.

7. Number and percentage of patients in the population of interest who have VTE prophylaxis started within 24 hours (or documented reason why contraindicated).

8. Number and percentage of patients in the population who survive evacuation from first MTF and the number who survive to final discharge from role 3/role 4.

DATA SOURCE

- Patient Record
- DoD Trauma Registry

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Hyperkalemia and Dialysis in the Deployed Setting (CPG ID: 52)

Provides recommendations for the management of patients with, or at risk for, acute kidney injury and hyperkalemia in the deployed environment.

SUMMARY OF CHANGES

1. Medical management for hyperkalemia flow chart and table.
2. Increase in treatment threshold to a K of 6.0 from 5.5 in tracking metrics.
3. Continuous Renal Replacement Therapy (CRRT) modality change from Continuous Venovenous Hemofiltration (CVVH) to Continuous Venovenous Hemodialysis (CVVHD).
4. CCRT flow chart.
5. Drug dosing recommendations for CVVHD.
6. Anticoagulation recommendation for CVVHD.
7. Recommendation for nutrition.
8. Addition of oral potassium binders.
9. Removed use of sodium bicarbonate for hyperkalemia.
10. Improvised dialysate fluid for CRRT and peritoneal dialysis.
11. Assessing fluid status recommendations.

BACKGROUND

Acute kidney injury (AKI) is a recognized complication of combat trauma. According to the Department of Defense Trauma Registry (DoDTR) data, AKI was listed as a complication in 0.6% of combat casualties. This is likely an under-representation of the real incidence as it was required to be listed as a complication in the available documentation. Smaller studies from two Role three facilities in theatre show AKI after combat trauma occurs in up to 34.3% of the most critically injured patients, usually within the first two days after injury.[1] This is likely closer to the real incidence in severely injured patients as a more thorough definition of AKI was used and is described below. Review of the DoDTR data did capture the number of patients that required renal replacement therapy (RRT) either in the form of continuous venovenous replacement (CRRT) or peritoneal dialysis (PD). Of the 558 patients with AKI listed as a complication, 112 or 20% required renal replacement. Of these 112 patients, 35 or 31% required RRT while still in theatre. In the recent conflicts in Iraq and Afghanistan, rapid evacuation out of theater ensured that the complications of AKI (including hyperkalemia) occurred further up the evacuation chain (Role 3-4), where RRT may have been available;[2] Furthermore, rapid damage control resuscitation and surgery likely decreased the rate of severe AKI. As a consequence, there are no recent data on the frequency of hyperkalemia following AKI in theater when experiencing delays in treatments and evacuations. However, evidence from prior conflicts suggests that up to one-third of combat casualties with oliguric renal failure developed severe hyperkalemia within four days of injury.[3] In future operations, military providers should be prepared for prolonged evacuation times.[4] AKI and life threatening hyperkalemia may be encountered at Role 3 facilities more frequently, where RRT is limited or non-existent. This is an important planning factor in future Large Scale Combat Operations (LCSO) where there may be multiple Role 3s and limited availability to move casualties compared to the previous conflict. AKI is classified by relative changes in creatinine and can be diagnosed with as little as a 0.3mg/dL increase in creatinine over a 48 hour (hr) period.[5] AKI can also be determined by decreased urine output (< 0.5 ml/kg/hr for at least 6 hours). While mild AKI can generally be managed with supportive care; more severe AKI [characterized by oliguria (<500 ml/day of urine output and/or <0.5 mL/kg/hr) or a doubling of serum creatinine] may require RRT. Therefore, providers caring for patients in austere or deployed environments should monitor patients for AKI and be prepared to expedite evacuation to a higher echelon of care, when necessary.

RECOMMENDATIONS

These recommendations are intended to temporize patients until they can be evacuated to a higher echelon of care with the full range of RRT capabilities.

ETIOLOGY OF HYPERKALEMIA

Providers in the operational setting should be proactive in correcting hyperkalemia. Rhabdomyolysis, dehydration (especially in the setting of Non-steroidal anti-inflammatory drugs), hypotension, packed red blood cells transfusions, sepsis, and urinary obstruction are a few causes of hyperkalemia encountered in the deployed setting.

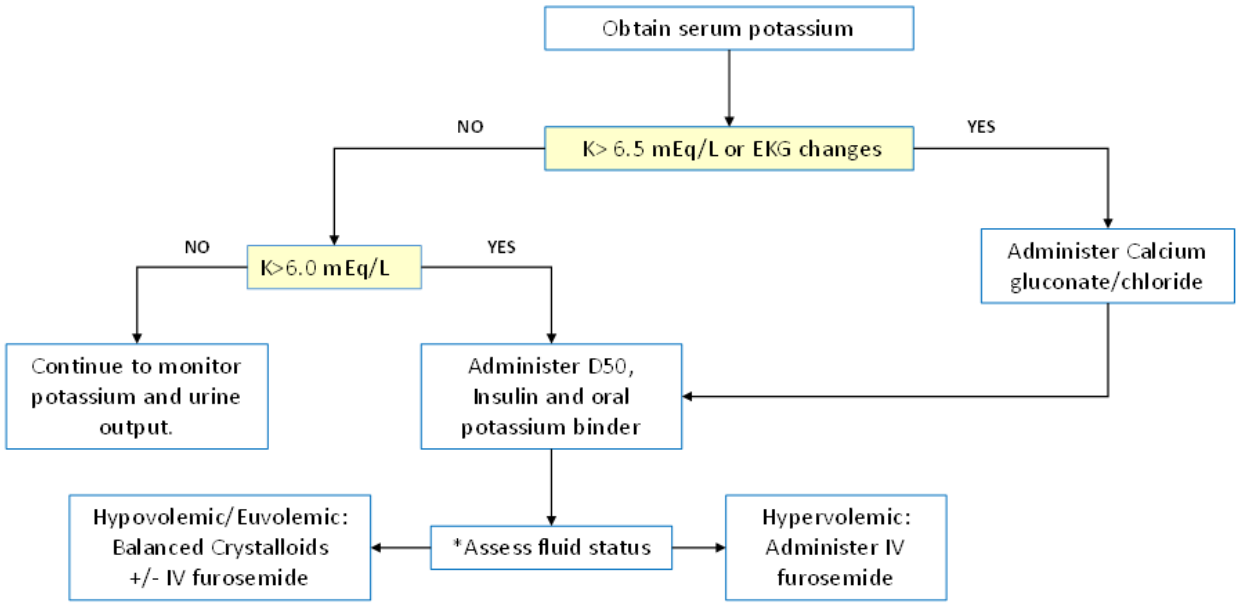
MONITORING

Monitor serum potassium, serum creatinine, hourly urine output, and an electrocardiogram (if available) in patients at risk for AKI and hyperkalemia.

MEDICAL MANAGEMENT

Medical therapy is the first step of AKI management with hyperkalemia. This includes cardiac membrane stabilization (with intravenous calcium chloride or calcium gluconate) and/or shifting potassium intracellularly (with insulin and glucose or a β-2-adrenergic agonist). Consider maneuvers to remove potassium with diuretics and potassium binding agents; usage may be limited by hemodynamic status, anuria, and bowel injuries. We suggest shifting potassium intracellularly when the potassium is greater than 6.0 milliequivalents per liter (meq/L) [with intravenous insulin and 50 percent dextrose (D50), with or without albuterol]. Take into account the clinical situation when determining when to treat hyperkalemia. For example, a rapid rise or impending evacuation should prompt consideration for shifting at a lower cut-off (i.e. 5.5meq/L). Calcium should be given if there is evidence or suspicion of clinically significant hyperkalemia and evidence of altered conduction on electrocardiogram such as: peaked T waves, widened QRS, flattened P waves, bradycardia, ventricular tachycardia, ventricular fibrillation, right and left bundle block, pseudo infarct, and Brugada pattern.[6,7,8] Calcium should also be considered empirically for a potassium concentration >6.5 meq/L. See Appendix A for a list of medications, routes of administration and recommended treatment order. The use of Balanced Crystalloids in the setting of hyperkalemia may seem contraindicated. However, through volume of distribution administering a potassium containing fluid which is lower than the patient's serum potassium will in fact lower the serum potassium concentration.[9] Providing a hyperchloremic crystalloids such as 0.9% normal saline will result in mineral acidosis thus worsening hyperkalemia.[10]

Figure 1. Medical management for hyperkalemia



**see Appendix E on assessing fluid status*

Table 1. Medical management for hyperkalemia

	Access	Monitoring	Therapies	Other Comments
Good	▪ 2 Large Bore IVs	▪ Frequent Clinical Checks ▪ Frequent Vital Signs ▪ Monitor urine output	▪ Calcium ▪ Balanced Crystalloids*	Crystalloids if no contraindication such as uncontrolled hemorrhage
Better	▪ 2 Large Bore IVs ▪ Foley Catheter	▪ Frequent Clinical Checks ▪ 12 lead EKG ▪ Foley to monitor urinary output (UOP) ▪ Glucometer	▪ Calcium ▪ Balanced Crystalloids* ▪ D50/Insulin ▪ Albuterol(neb) ▪ Furosemide	Note that in the absence of potassium monitoring, these would only be considered if characteristic EKG or peri-arrest patient with high clinical suspicion.
Best	▪ 1-2 Large Bore IVs ▪ Central Venous Catheter ▪ Foley Catheter	▪ Frequent Clinical Checks ▪ Continuous EKG Monitoring ▪ 12 lead EKG ▪ Foley to monitor UOP ▪ Glucometer ▪ Point-of-care labs	▪ Calcium ▪ Balanced Crystalloids* ▪ D50/Insulin ▪ Albuterol (neb) ▪ Furosemide ▪ Potassium binder	Use caution with furosemide as this may exacerbate hypotension in acute resuscitative phase. See Figure 1 flow chart.

**Balance Crystalloids= Lactated Ringers or Plasmalyte ®*

FAILURE OF MEDICAL MANAGEMENT

In the experience of the authors, the most common reason for starting RRT for patients with AKI in the deployed setting is hyperkalemia resistance to medical management. A potassium level greater than 6 meq/L, despite medical management, should prompt consideration of RRT with either the NxStage System One or acute PD. Occasionally, patients may require RRT in theater for other indications, such as acidemia or severe volume overload. The following detailed methods can effectively temporize patients with these indications as well.

SEVERE HYPERKALEMIA & NXSTAGE SYSTEM ONE

If available, use the NxStage System One for severe hyperkalemia that does not respond to medical management. To utilize this system, the patient must have central venous access with a dialysis catheter, the machine must be setup and the prescription must be entered. There are five components to a CRRT prescription: mode, blood flow rate, replacement fluid, replacement fluid rate, and ultrafiltration rate. See Appendix C for a suggested initial prescription.

Central Venous Access

Place a hemodialysis catheter, prior to initiation. In terms of location, follow guidelines,[5] which suggests the first choice of access is the right internal jugular vein (with a 12-14 French, 15cm catheter), because this location has been associated with the lowest rates of catheter dysfunction.[11] The second choice is the femoral vein (with a 20-25cm catheter). The last choice is the left internal jugular vein (with a 20cm catheter) because it is associated with the highest rates of catheter dysfunction.[11] If possible, avoid the

subclavian veins. Lines in this location often result in subclavian stenosis, which can complicate or preclude future dialysis access in patients at risk for the development of end stage renal disease.[12,13]

Setup

The Set up – Initiate – Make connections – Program – Launch treatment – End (SIMPLE) instructions are displayed on the NxStage computer screen once the machine is turned on. These instructions are quite detailed and, if followed closely step-by-step, will guide the provider through priming the cartridge, putting the patient on the machine, entering the prescription and ending the treatment once it is complete. Ideally, providers that deploy to a location with the NxStage System One should receive training on the setup and use of the system prior to deployment. The instructions are straightforward enough to allow an inexperienced physician or nurse to perform a treatment within the deployed setting.

Mode

The NxStage System One can provide continuous venovenous hemodialysis (CVVHD), which is the recommended form of CRRT for the down-range setting. Complete this by connecting the two green ports as specified in the step-by-step priming instructions.

Blood Flow Rate

The minimum blood flow rate is 200ml/minutes (min) and should be increased to 400ml/min if possible. A faster blood flow rate will decrease the likelihood of blood clotting the filter. The most common limitation for increasing the blood flow rate is the pressure required to draw blood out of the dialysis catheter. If this pressure becomes too negative, the machine will alarm and stop the treatment. This alarm is often due to catheter port suction against the vessel wall. If this occurs, decrease the blood flow rate until the machine no longer alarms. Catheter manipulation, line reversal, or line relocation may solve this issue. To manipulate the catheter, using the sterile technique, grasp the catheter proximal to the sutured/secured hub and twist it 180 degrees. This may move the blood flow ports away from a vessel wall. To reverse the lines, first stop the machine and clamp both the blood lines and both the dialysis catheter ports. Then disconnect the blood lines and re-connect them to the dialysis catheter ports opposite of how they were previously connected. If these efforts fail, consider an alternate insertion site for the catheter.

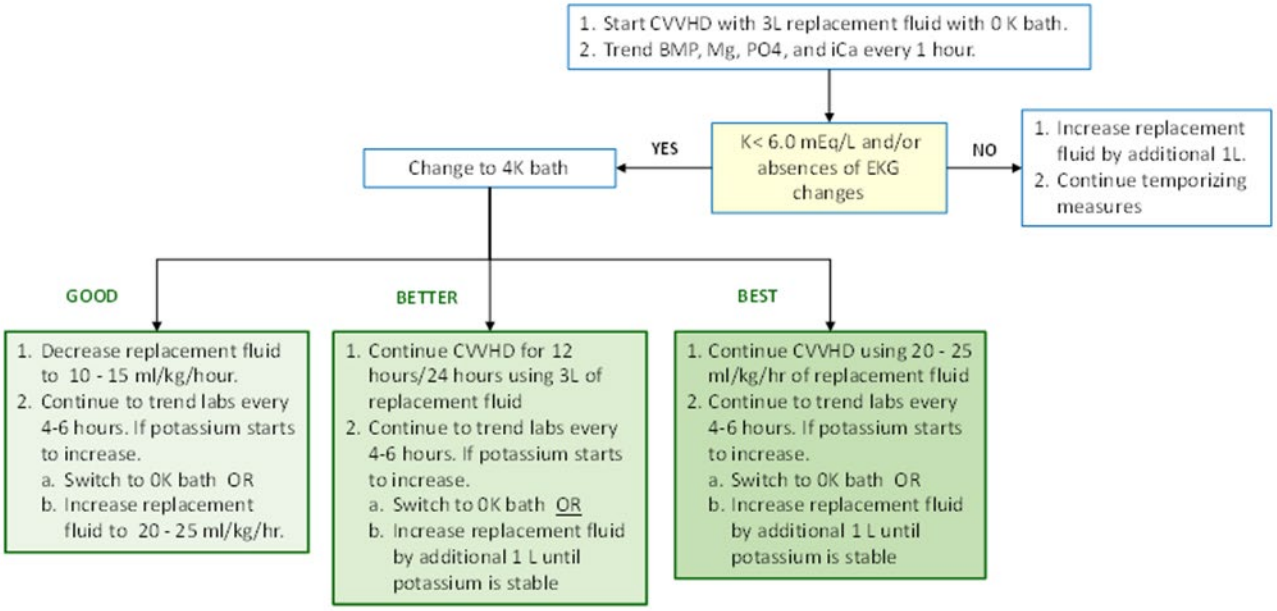
Dialysate Fluid

There are several commercially made replacement fluids. Regardless of the specific brand available, there will be 0meq/L potassium (0K) and 4meq/L potassium (4K) options. Since CRRT in the deployed environment is usually initiated for hyperkalemia, we suggest starting with the 0K fluid and following the potassium concentration every hour. Once the potassium decreases to <6.0 meq/L and/or absences of EKG changes, the patient can be transitioned to the 4K replacement fluid. It is important to note that the replacement fluid bags have two separate compartments, to avoid precipitation of calcium and bicarbonate. It is vital that the seal between the two compartments is broken in the manner detailed in the step-by-step instructions on the NxStage System One display screen. If commercial solutions are not available, replacement fluids can be made (See Appendix E).[14] Despite which fluid is in use, closely monitor ionized calcium, magnesium and phosphate (every 6 hours) if possible and replace as needed.

Dialysate Flow Rate

The dialysate flow rate is the rate at which the machine infuses dialysate fluid and it is the primary determinant of clearance. Initially, we suggest starting with a dialysate flow rate of 3L/ hour with hourly monitoring of serum potassium. If the potassium fails to improve, increase the dialysate flow rate. With the NxStage System One, the maximum dialysate flow rate is dependent on the blood flow rate. If high clearances are needed, increase the blood flow rate to 400ml/min and set the dialysate flow rate as high as the machine allows (8.4L per hour). If this fails, the patient likely has severe ongoing tissue necrosis and you need to consider surgical re-evaluation for debridement. Reduce the dialysate flow rate or consider stopping CVVHD once you have reached a reasonable serum potassium level in order to conserve resources.

Figure 2. CRRT management for hyperkalemia



1. Start CVVHD with 3L replacement fluid with 0 K bath.
2. Trend BMP, Mg, PO4, and iCa every 1 hour.

GOOD
BETTER
BEST
1. Decrease replacement fluid to 10 - 15 ml/kg/hour.
2. Continue to trend labs every 4-6 hours. If potassium starts to increase.
a. Switch to 0K bath OR
b. Increase replacement fluid to 20 - 25 ml/kg/hr.
1. Continue CVVHD for 12 hours/24 hours using 3L of replacement fluid
2. Continue to trend labs every 4-6 hours. If potassium starts to increase.
a. Switch to 0K bath OR
b. Increase replacement fluid by additional 1 L until potassium is stable
1. Continue CVVHD using 20 - 25 ml/kg/hr of replacement fluid
2. Continue to trend labs every 4-6 hours. If potassium starts to increase.
a. Switch to 0K bath OR
b. Increase replacement fluid by additional 1 L until potassium is stable

Ultrafiltration Rate

This is the rate at which the machine removes volume from the patient. For example, if this is set at 100ml/hr, 2.4L will be removed from the patient over the next 24 hours. In the absence of overt hypervolemia, we suggest initially setting the ultrafiltration rate to 0 or equal to all of the patient's hourly fluid input (IV fluids, antibiotics, etc.). However, if the patient has significant volume overload (e.g., pulmonary edema), this can be titrated to achieve a net negative fluid balance of 1-2L per day (all quantifiable inputs minus all quantifiable outputs).

Since these patients have experienced recent trauma, often with associated coagulopathy, and citrate anticoagulation is not available in the deployed setting, we suggest not anticoagulating patients for the sole purpose of CRRT. Should filter clotting become an issue, the following maneuvers may be useful: 1) increase blood flow rate or 2) decreasing/stopping ultrafiltration rate to decrease hemo-concentration. Another strategy that is considered safe is adding a pre-filter (into the blood line coming out of the patient and going to the NxStage System One) infusion of normal saline at 100 ml/hr (you need to account for this input when calculating ultrafiltration rate) to help dilute blood in dialyzer. As a

last resort and only if there is recurrent clotting compromising the delivery of this therapy and the patient is not a bleeding risk, you may consider an infusion of 500 units per hour of heparin. This should be infused pre-filter as previously noted. If needed, this can then be titrated to achieve an aPTT 1.5-2 times normal.[15]

DRUG DOSING

General antimicrobial dosing for CVVHD (recommendations below in Table 2 are based on data using CVVH, possible increase in drug clearance with CVVHD modality).

Table 2. General antimicrobial dosing for CVVHD

Antibiotic	Recommend dose for CVVHD
Vancomycin	20 mg/lg/24hrs as continuous infusion
Daptomycin	8 mg/kg every 48 hours
Piperacillin/Tazobactam	3.375 g every 6 hours, each dose infused over 3 hours
Cefepime	Loading dose of 2,000 mg followed by 1,000-2000 mg every 12 hours
Meropenem	1 g every 8 hours
Imipenem/cilastatin	500 mg every 6 hours
Amikacin	Loading dose of 10 mg/kg, then 7.5 mg/kg every 24-48 hours
Levofloxacin	Loading dose of 500-750 mg then 250 mg every 24 hours

NUTRITION

Patients on CRRT have an increased nutritional demand due to clearance delivered by CRRT. Higher dose clearance requires increased nutrient demands.

Table 3. Nutritional recommendations for patients on CRRT

	Recommendation	Notes
Energy requirements	25-35 Kcal/kg	Fluids containing lactate, citrate, and acetate can also contribute to caloric intake.
Protein Requirements	1.5 g/kg/day	Can consider glutamine supplementation 0.3-0.5 g/kg/day. If BUN continues to rise despite CRRT consider reduction in protein intake.

ACUTE PD

If patients do not respond to medical management, and NxStage System One is not available, consider acute PD.

While its use has been supplanted by CRRT in most developed nations, PD is an established treatment for AKI with electrolyte disturbances such as hyperkalemia.[16] PD relies on the diffusion and convection of solutes from the blood into a fluid across the peritoneal membrane. For the purposes of potassium clearance, a fluid that is low in potassium is infused into the peritoneal space. Potassium then flows down its concentration gradient from the blood and extracellular space into this fluid. Once equilibration is achieved (i.e. the concentration in the blood and fluid are equal) no further potassium goes into the fluid. Therefore, the fluid must be exchanged periodically to maintain clearance.

Because recent abdominal surgery is considered a relative contraindication to PD,[17] the efficacy of PD and the complications associated with PD in trauma patients that have undergone laparotomy and/or have bowel in discontinuity are largely unknown. However, there are case reports of PD being used in combat casualties with recent laparotomy.[20] If no other forms of renal replacement therapy are available and the patient cannot be evacuated to a higher echelon of care, consider PD, even in patients without an intact peritoneal lining.

In order to perform PD, access to the peritoneal space is needed. Once access is established, there are three components to a PD prescription: fluid type, exchange volume, and dwell time.

Catheter Placement

Under normal circumstances, specialized catheters are used for PD. These are not usually available in the deployed setting, which require available supplies to be repurposed. Jackson-Pratt (JP) abdominal drains and pediatric chest tubes have both been used as improvised PD catheters in theater.[18,20] Nasogastric tubes central lines, suprapubic and urinary catheters have also been recommended as improvised catheters.[16,18] While catheters can be placed via a variety of methods (including modified Seldinger and laparoscopic techniques), most patients in the forward deployed environment will require open surgical approaches.[20] Under ideal circumstances, PD catheters should be tunneled in order to decrease the risk of peritonitis.[16] This may not be an option in the austere, forward deployed environment where the use of stoma appliances as a protective dressing to prevent the described infections.[20]

Fluid Type

While specialized PD fluids are made commercially, they are not normally available in deployed locations. However, a variety of fluids can be used for field expedient PD (Refer to Appendix D for this section). If the indication is hyperkalemia, use a solution with a potassium concentration of 0 at the initiation of PD. Monitor the patient's potassium level and once normalized, change the fluid to a concentration of ~4meq/L by using one of the alternate fluids. Note that in the setting of shock or liver failure, a solution with bicarbonate (not lactate) will reverse acidemia more rapidly.[19] If acidemia persists after correction of potassium in patients in shock, ~4meq/L of potassium should be added to the "potassium free solution" of choice to avoid using lactate as a buffer. The amount of fluid removed by PD is determined by two factors: 1) the amount of time the fluid is in the abdomen and 2) the concentration of dextrose in the solution. As others have recommended,[15] we suggest that a concentration of ~1.5% dextrose be used for patients that are euvolemic or hypovolemic. For patients that are moderately or severely volume overloaded, we suggest ~2.5% and ~4.5% dextrose concentrations, respectively. Note that a 4.5% dextrose fluid can remove volume very quickly (up to 1L in 4 hours),[15] therefore you should limit its use to hemodynamically stable patients with severe, life-threatening pulmonary edema.

Exchange Volume

The "exchange volume" is the volume of fluid infused into the peritoneal space. Removing the fluid after the dwell and instilling fresh fluid is referred to as an "exchange." We recommend starting with a volume of 1L per exchange for and then increasing to 2L per exchange if tolerated. We recommend continuous exchanges until potassium is <6.0 mEq/L; then can decrease to 5 cycles of 2L exchanges. The volume infused may be limited by fluid leakage around the surgical site, especially in patients with large laparotomy incisions or open abdomens. To avoid leakage, keep the patient in the supine position during PD.

Dwell Time

The length of time that the fluid is allowed to sit in the peritoneal space between exchanges is known as the "dwell time." We recommend frequent exchanges (defined as an initial dwell time of 1 hour) until the initial therapeutic goal has been achieved (e.g., potassium normalized or acidemia reversed), at which point the dwell time can be extended to every 2-4 hours with close monitoring.

In the forward deployed setting, the use of PD can be complicated by fluid leakage (especially if the abdomen must be left open) and also by the development of abdominal compartment syndrome with fluid infusion. These may severely limit the volume of fluid that can be infused and allowed to dwell. In this case, the fluid can be continuously exchanged.[20] In practice, this means instilling fluid into the peritoneum from one site (e.g., from a pediatric chest tube or JP drain) while simultaneously removing fluid from another site (e.g., a different drain, or wound vac if available.) If continuous exchange of fluid is utilized, the inflow and outflow ports in the peritoneal space should be physically separated as much as possible to maximize the surface area that the fluid passes by as it goes from the inflow catheter to the outflow catheter. The outflow port should if possible be in the most dependent part of the abdomen (the pelvis).

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

Patients with acute kidney injury or hyperkalemia (potassium > 6.0 or hyperkalemia diagnosis code or documentation of EKG changes consistent with hyperkalemia).

INTENT (EXPECTED OUTCOMES)

1. All patients with K > 6.0 and/or EKG changes consistent with hyperkalemia receive appropriate medical treatment at the same level of care where diagnosed. (See drugs listed in Appendix A.)
2. All patients with persistent hyperkalemia despite medical management receive RRT (CRRT or peritoneal dialysis) or documenting why RRT is not implemented.
3. Indication for initiation RRT is documented.

PERFORMANCE/ADHERENCE MEASURES

- Number and percentage of patients in the population of interest who receive medical treatment for hyperkalemia at the same level of care where diagnosed.
- Number and percentage of patients who receive RRT who have the indication for RRT documented.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance and PI monitoring at the local level with this CPG.

APPENDIX A: INITIAL MEDICAL MANAGEMENT FOR HYPERKALEMIA

Drug/ Treatment	Dose & Route of Administration	Mechanism of Action	Time to Onset	Duration of Effect	Caution/Contraindication	Other Comments
Stabilize Cardiac Membranes						
Calcium gluconate	1000mg=one 10ml "amp" of 10% (100mg/mL) solution; infused IV over 2-3 mins	Stabilizes myocyte membrane electrical activity	Immediate	30-60 mins	Caution if pre-existing hypercalcemia	Can be administered via peripheral IV; repeat in 5 mins for persistent EKG changes
Calcium chloride	1000mg=one 10ml "amp" of 10% (100mg/mL) solution; infused IV over 2-3 mins	Stabilizes myocyte membrane electrical activity	Immediate	30-60 mins	Administration via central line preferred (can damage small vessels, cause tissue necrosis); caution if pre-existing hypercalcemia	Repeat in 5 mins for persistent EKG changes
Shift Potassium Intracellularly						
Insulin, regular	Give 50 mL 50% dextrose first unless blood glucose is >250. Then give insulin 10 units by IV bolus.	Shifts potassium intracellularly by way of Na-K ATPase pump	10-20 mins	4-6 hr	Caution if hypoglycemia. Insulin is renally secreted in setting of anuria/oliguria can cause prolonged hypoglycemia.	Check blood glucose within one hour of administration. If oliguric/anuric can consider starting D5W gtt to prevent hypoglycemia. Insulin should be kept cold until use, consider packing in personnel insulin carriers.
Albuterol	10 mg nebulized, over 10 mins	Shifts potassium intracellularly by way of Na-K ATPase pump	20-30 mins	1-2 hr	Can cause tachycardia	Has additive effect with insulin tx
Potassium Binders						
BEST Sodium Zirconium Cyclosilcate (Lokelma)	10 gram (in water) PO TID for 48 hours, followed by 10 g PO daily	Mechanism not fully understood, exchanges hydrogen and sodium for potassium in small and large intestines	1 hour	Variable (up to 48 hrs of treatment time)	No studies conducted on patient with bowel obstruction or impaction. Avoid in patients with severe constipation, bowel obstruction or impaction.	Preferred oral potassium binder Monitor for signs of edema, can increase diuretics if indicated.
BETTER Patiromer (Veltassa)	8.4 g/16.8g (in water) PO once daily	Increases potassium removal by fecal excretion, exchanges calcium for potassium in the large intestine.	~7 hours	24 hours	Avoid in patient with bowel obstruction or severe constipation. Can cause Hypomagnesemia.	May decrease effectiveness of oral Ciprofloxacin. Administer Ciprofloxacin 3 hours before or after Patiromer. Patiromer must be refrigerated or used within 3 days after removed from refrigeration.
GOOD Sodium polystyrene sulfonate (Kayexalate)	30 grams PO	Exchanges sodium for potassium in the large intestine	>2 hours	Variable	Case reports of colonic necrosis; avoid in setting of bowel obstruction or following bowel injury or surgery; may be of limited utility in setting of severe hyperkalemia.	Can repeat every 4-6 hours; consider initial dose of 45-60 grams in body weight >80 kg
Promote Kaliuresis						
Furosemide	40mg IV	Impairs renal potassium reabsorption	5 mins	2 hours	If hypotensive or volume depleted consider administration with balanced crystalloid and IV diuretics.	May require larger does (up to 200mg) or be ineffective in setting of acute kidney injury.

APPENDIX B: CONTINUOUS RENAL REPLACEMENT THERAPY - NXSTAGE SYSTEM ONE

Suggested starting prescriptions and dosage

	Recommendation	Notes
Mode	CVVHD	CVVHD should be considered over CVVH because it is more efficient per liter of volume used.
Blood Flow Rate	200-400 ml/min	The blood flow rate should be increased as much as tolerated by the access pressures and machine alarms to avoid clotting. We suggest maintaining flows of at least 200 cc/min.
Replacement Fluid Type	0K, 4K	If 0K or 4K fluid is not available, CRRT can be performed using lactated ringer, Plasmalyte or the improvised solutions for peritoneal dialysis. Monitor BMP, magnesium, ionized calcium, and phosphate.
Replacement Fluid Rate	3L per hour initially	See flow chart under replacement fluid rate for further guidance.
Ultrafiltrate Rate	0 ml/min	If desired, fluid can be removed via ultrafiltration. In the acute setting, barring overt hypervolemia, fluid removal should be avoided. However, consider setting the ultrafiltration rate to the patient's hourly "In's" to avoid hypervolemia.

APPENDIX C: IMPROVISED SOLUTIONS - CONTINUOUS RENAL REPLACEMENT THERAPY

	0.45% NaCl	8.4% NaHCO3	50% Dextrose	3% NS	50% MgSO4	CaCl2
Volume (mL)	1000	40	2.5	80	0.3	2.5

* Note that this fluid does not contain potassium or phosphate supplementation.

APPENDIX D: IMPROVISED SOLUTIONS FOR PERITONEAL DIALYSIS

Starting Fluid	Addition(s)	Ending Concentrations
Potassium Free Solutions		
1 Liter ½ Normal Saline Na 77 mEq/L, Cl 77 mEq/L	40ml of 8.4% Bicarbonate 35ml of 50% Dextrose 60ml of 3% Saline	Na 130 mmol/L, K 0 mmol/L, Ca 0 mg/dL, Cl 95 mmol/L, bicarbonate 35 mmol/L, Osm 338 mOsm/kg, Dextrose 1.54%
1 Liter ½ Normal Saline Na 77 mEq/L, Cl 77 mEq/L	40ml of 8.4% Bicarbonate 60ml of 50% Dextrose 65ml of 3% Saline	Na 129 mmol/L, K 0 mmol/L, Ca 0 mg/dL mmol/L, Cl 95 mmol/L, bicarbonate 34, Osm 388 mOsm/kg, Dextrose 2.57%
1 Liter ½ Normal Saline Na 77 mEq/L, Cl 77 mEq/L	43ml of 8.4% Bicarbonate 105ml of 50% Dextrose 75ml of 3% Saline	Na 130 mmol/L, K 0 mmol/L, Ca 0 mg/dL, Cl 94 mmol/L, bicarbonate 35 mmol/L, Osm 476 mOsm/kg, Dextrose 4.29%
Potassium Containing Solutions		
1Liter Lactated Ringers Na 130 mEq/L, K 4 mEq/L, Ca 2.7 mEq/L, Cl 109 mEq/L, Lactate 28, Osm 273 mOsml/L	30ml 50% Dextrose	Na 126 mmol/L, K 3.9 mmol/L, Ca 2.6 mg/dL, Cl 106 mmol/L, Lactate 27 mmol/L, Osm 339 mOsm/kg, Dextrose 1.46%
1Liter Lactated Ringers Na 130 mEq/L, K 4 mEq/L, Ca 2.7 mEq/L, Cl 109 mEq/L, Lactate 28 mEq/L, Osm 273 mOsml/L	53ml of 50% Dextrose 10ml of 3% Saline	Na 127 mmol/L, K 3.8 mmol/L, Ca 2.5 mg/dL, Cl 107 mmol/L, Lactate 26 mmol/L, Osm 392 mOsm/kg, Dextrose 2.49%
1Liter Lactated Ringers Na 130 mEq/L, K 4 mEq/L, Ca 2.7 mEq/L, Cl 109 mEq/L, Lactate 28 mEq/L, Osm 273 mOsml/L	95ml of 50% Dextrose 25ml of 3% Saline	Na 128 mmol/L, K 3.6 mmol/L, Ca 2.4 mg/dL, Cl 109 mmol/L, Lactate 25 mmol/L, Osm 481 mOsm/kg, Dextrose 4.24%

*1L fluid bags may contain extra fluid (40-60ml), this additional volume is not included in these calculations as it will not make a significant clinical difference.

These suggested fluids are based on what is likely to be available in the forward deployed setting. In case other fluids need to be improvised, an example of how these solutions were derived may be instructive. These calculations are based on the total amount of the substance divided by the total volume. For example, the Na concentration in the first fluid in the table:

1. Total amount of Na: amount in ½ NS (77meq/L x 1L=77meq) plus amount in 8.4% bicarbonate (1000meq/L x 0.04L= 40meq) plus amount in 3% saline (513meq/L x 0.06L= 30.78meq). Therefore, total amount is 77+40+30.78=147.78. Note that there is no Na in 50% dextrose.
2. Total volume: Volume of ½ NS plus volume of 8.4% bicarbonate plus volume of 50% Dextrose plus volume of 3% saline. 1+0.04+0.035+0.06=1.135 L.
3. Dividing the total amount of Na (147.78 meq) by the total volume (1.135L) equals 130.20264 or about 130 meq/L.

APPENDIX E: ASSESSING FLUID STATUS

	Hypervolemia	Euvolemia	Hypovolemia
Cardiovascular	Normotension/Hypertension, Strong Peripheral Pulses, Negative PLR test, Peripheral Edema*	Normotension, Normal Peripheral Pulses, indeterminant PLR	Hypotension, Weak/diminished Peripheral Pulses, Positive PLR test, Pallor, Tachycardia
Pulmonary	Crackles, Dyspnea, Pulmonary Edema, Pleural Effusion*	Eupnea, Clear Breath Sounds	No specific findings
Ultrasound Findings	Pulmonary B lines, Inferior Vena Cava (IVC) remains completely dilated on inspiration, Pleural Effusion*, Ascites*	Pulmonary A lines, Sea Shore Sign, Inferior Vena Cava (IVC) compresses less than 50% on inspiration	Positive eFAST exam, Collapsing or "Kissing" ventricles, IVC compresses more than 50% on inspiration

**- indicates late findings*

PLR= Passive Leg Raise. To conduct PLR: while patient is lying flat obtain blood pressure, then raise legs to 45 degrees and hold for 60-90 seconds. After holding for 60-90 seconds obtain blood pressure. Positive PLR test is when difference of systolic blood pressures from diastolic blood pressures is equal to or greater than 10%.

Limitations: Intra-abdominal hypertension, head trauma/increased ICP, lower extremity Deep vein thrombosis (DVT), amputated leg.

Assessing volume status is difficult, even among medical professionals. The above stated clinical and imaging findings are used to serve as a guideline and volume status cannot be determined based on one sole finding, rather a combination of clinical and imaging findings.

APPENDIX F: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Hypothermia: Prevention and Treatment

This document provides updates to the Hypothermia Prevention Monitoring and Management CPG from 2012 and is applicable from the pre-hospital phase of care and beyond.

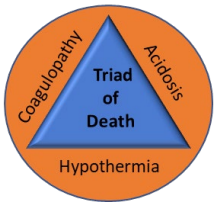
HYPOTHERMIA

PREVENTION & TREATMENT

Published by the Joint Trauma System,
the DoD Center of Excellence for Trauma

● Prehospital ● Tactical Combat Casualty Care ● En Route Care ●
Prolonged Casualty Care ● Tips & Tricks ● Troubleshooting

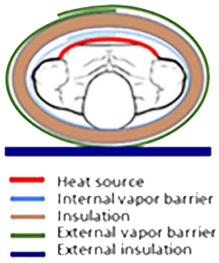
Hypothermia is a key contributor in the Triad of Death



Trauma-induced Hypothermia

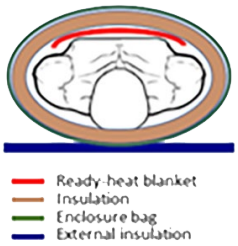
mild: 34-36 °C
moderate: 32-34 °C
severe: <32 °C

- ✓ **Replace wet clothing** with dry clothing
- ✓ **Monitor patient's temperature** during rewarming. Convert to continuous temperature monitoring.
- ✓ **Warm resuscitation fluids/blood products** to 38-42 °C with a flow rate up to 150 ml/min



Use passive and active methods of rewarming

- Passive warming: utilizing the patient's heat generation via shivering/metabolism.
- Active warming: applying an external heat source



METRICS

- Temperature and route will be documented on all patients upon admission and discharge.
- Core temperatures are obtained on patients with temperature < 97° F and > 100° F.
- Warming measures and sustainment of core temperature > 96°.F are initiated on all patients.

Defense Health Agency
JOINT TRAUMA SYSTEM ®

Clinical tips based on the Hypothermia: Prevention and Treatment CPG, Jun 2023, published by the Joint Trauma System.

JTS CPGs : HTTPS://JTS.HEALTH.MIL/INDEX.CFM/PI_CPGS/CPGS

SUMMARY OF CHANGES

1. Incorporates Tactical Combat Casualty Care (TCCC) Guidelines for Hypothermia from 2021.
2. Expands prevention of trauma-induced hypothermia to include not only trauma patients in hemorrhagic shock, but also burns and cerebrospinal injuries.
3. Outlines characteristics of hypothermia prevention and treatment systems that can be utilized in addition to the more widely used system, the Hypothermia Prevention and Management Kit (HPMK) and the Heat Reflective Shell (HRS).
4. Provides option if unable to remove wet clothing to include the enclosure of the casualty with a vapor barrier over the wet clothing.
5. Recommends upgrading the HPMK to an insulated system as soon as possible as it is non-insulated and therefore only suitable for short term hypothermia prevention.
6. Provides specific target for warm resuscitation fluids/blood products to 38-42 degrees Celsius.
7. Adds Prolonged Casualty Care (PCC) guidelines to the CPG.
8. Expands Field Expedient 'Tricks of the Trade' in the CPG.

BACKGROUND

Hypothermia, coagulopathy, and acidosis are the physiological derangements constituting the "triad of death" in trauma patients.[1–4] Here, we use the term trauma-induced hypothermia (TIH) as it relates more specifically to combat trauma including hemorrhagic shock, cerebrospinal injury, and burns - all of which lead to a significantly increased risk of mortality and presents as a separate, more severe entity than non-traumatic or environmental hypothermia. TIH is a ubiquitous concern regardless of the environment as it can occur even in warm climates, as has been the experience in the Middle East.[5]

The Hypothermia CPG, initially published in 2006, was one of the first JTS CPGs. Prior to this, the rate of hypothermia (Temp <97 F) in patients arriving to the first role of care was as high as 15.42% in 2004. The rate initially dropped by over half to 7.26%. While it slowly increased again, it should be noted that missing temperature data in the DoD Trauma Registry (DoDTR) was as high as 42% when large volumes of casualties were being seen in 2003. The rate of missing data dropped significantly when the CPG was published yet remained in the 10-20% range. It is unclear if the true incidence was higher before 2006, but this potentially shows a Hawthorne effect and the effectiveness of tracking information to inform clinical practice. Figure 1 shows the trend in hypothermia by U.S. Military patients by year at any medical treatment facility (MTF). The purpose of this CPG is to provide guidance for the prevention and management of TIH in the combat casualty throughout the escalating roles of care.

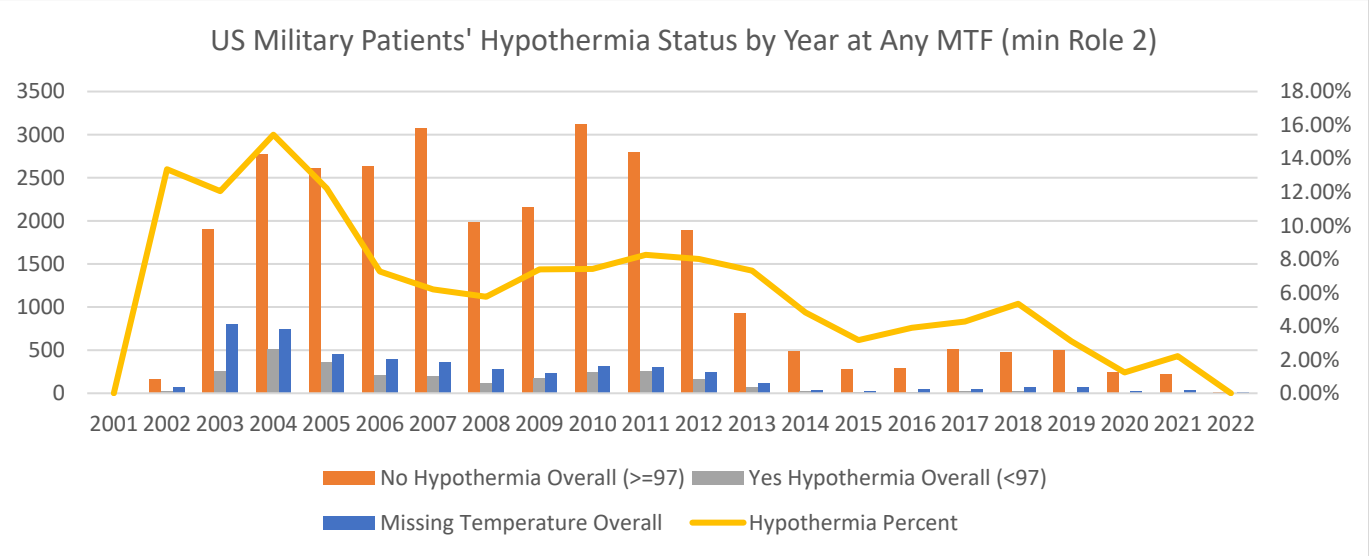
Current literature suggests that about one to two-thirds of trauma patients are hypothermic upon presentation to the emergency department. The mortality of hypothermic patients is approximately twice that of similarly injured normothermic patients.[7-10] In another large study of trauma patients requiring massive transfusion, hypothermia (< 36 deg C) on arrival was an independent predictor of mortality and associated with increased blood product

TIH is classified as mild: 34-36 °C, moderate: 32-34 °C, and severe: <32 °C.[6]

consumption.[11-13] Furthermore, studies in civilian trauma have shown >80% of non-surviving patients arrived hypothermic with a core temperature < 34 deg C.[12] In both civilian and military trauma, 100% mortality has been demonstrated when core temperature reached < 32 deg C.[14,15] When hypothermic patients fall below the thermoregulatory threshold for shivering (around 30 deg C), shivering heat production ceases. Therefore, these patients have lost the ability to generate heat and will continue to cool unless actively rewarmed by external sources.[16] This can be further exacerbated by pharmacologic treatment with sedatives and paralytics.[17,18]

Innovation and improved outcomes-based research over the past two decades have improved survivability via addressing coagulopathy and acidosis .[1,5,19–22] Early recognition and treatment of hypothermia is an equally important consideration that begins at the point of injury and should be implemented for all combat casualties, particularly patients at risk of experiencing shock. As it is labor and resource intensive to re-warm a casualty, measures to prevent hypothermia should begin as soon as possible with thermal wraps and warmed resuscitation products.[5,23,24] There are varying degrees of abilities and resources availability at each echelon role of care, which are discussed in the following sections.

Figure 1. DoDTR Hypothermia Rate in US Combat Casualties (CENTCOM/AFRICOM) from 2001 to 2022.



The highest percentage of hypothermia occurred in 2004. The first hypothermia CPG was published in 2006. Over time the missing temperature recordings from the records decreased and starting in 2014, the percentage of combat casualty with hypothermia was less than 5%.

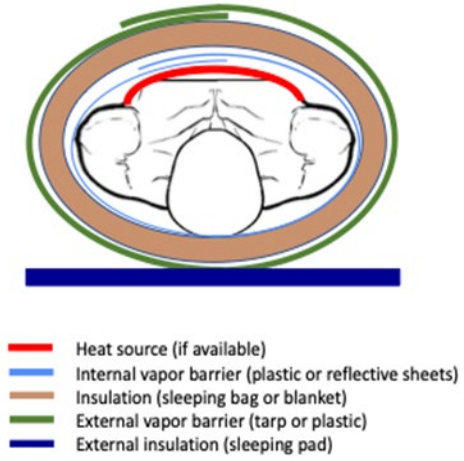
TREATMENT

PREHOSPITAL – TCCC

1. Take early and aggressive steps to prevent further body heat loss and add external heat, when possible, for both trauma and severely burned casualties.
2. Minimize casualty's exposure to cold ground, wind, and air temperatures. Place insulation material between the casualty and any cold surface as soon as possible. Keep protective gear on or with the casualty if feasible.
3. Replace wet clothing with dry clothing or another thermal barrier (i.e. sleeping bag), if possible, and protect from further heat loss. If unable to replace the dry clothing, wrap an impermeable vapor layer around the casualty. Leave the vapor barrier in place until a warm environment has been reached.
4. Place an active heating blanket on the casualty's anterior torso and under the arms in the axillae (to prevent burns, do not place any active heating source directly on the skin or wrap around the torso). Avoid placing the heat in high pressure areas (i.e. on the back of a supine patient). Regularly monitor the skin under these areas for burns. [25,26,27] See below for information on hypothermia wraps.
5. Enclose the casualty with the exterior impermeable enclosure bag. As soon as possible, upgrade hypothermia enclosure system to a well-insulated enclosure system using a hooded sleeping bag or other readily available insulation (i.e. wool blankets) inside the enclosure bag/external vapor barrier shell. The HPMK is non-insulated and therefore suitable only for short term hypothermia prevention, especially in cold climates.
6. Pre-stage an insulated hypothermia enclosure system with external active heating for transition from the non-insulated hypothermia enclosure systems; improve upon existing enclosure system when possible.
7. Use a battery-powered warming device to deliver IV resuscitation fluids, in accordance with current TCCC guidelines, at flow rate up to 150 ml/min with a 38°C output temperature. (See Appendix A.)
8. Protect the casualty from exposure to wind and precipitation on any evacuation platform.
9. The priority remains the recognition of shock and implementation of heat-loss prevention techniques as outlined above. Rewarming hypothermic patients can be achieved passively (utilizing the patient's heat generation via shivering/metabolism) and actively (applying an external heat source). If available, active re-warming should be initiated along with passive warming interventions.
10. Active heating: there are no contraindications other than do not use on a heat casualty or those not at risk for hypothermia.[28,29] See Figure 2 for the indications, contraindications, and other considerations for active rewarming below.
11. Regarding extremity/trauma and tourniquets, research is ongoing regarding the use of extremity tourniquets.[30] Priority in TIH is to prevent additional core cooling to mitigate the effects of shock, hypothermia, coagulopathy, and acidosis. Providers may consider leaving the extremity with a tourniquet outside of the insulating wrap, in order to monitor for re-bleeding. This is not recommended as standard practice as the priority should be on the life saving measures of TIH prevention.
12. Utilize an insulated hypothermia wrap with an active heating source for all potentially hypothermic trauma patients. Systems that include more insulation and active heating sources perform better for treating/preventing hypothermia but may present limitations when considering portability for field applications.[5,24] One of the more widely used systems due to portability, cost, and effectiveness is the HPMK which contains the Ready-Heat Blanket (RHB) - an active warming source and the HRS - essentially an impermeable vapor layer (previous version was the Blizzard blanket).

13. Other options include user assembled kits or commercial hypothermia kits, but the recommended characteristics of any hypothermia prevention/treatment system are outlined below. A list of active and passive external rewarming options for field use are shown in (Table 2 - Appendix A).
14. Burrito wrap concept with 5 layers as referenced per Bennet et al.
15. Active heat source applied to the torso in the following order of precedence: axillae, chest, back. These are the areas with the highest potential for heat transfer.[24,25,31] The heat source should not be in direct contact with the patient's skin.
16. Internal vapor layer (plastic or foil sheets)
17. Hooded sleeping bag or other insulation (wool blankets)
18. Complete with an outer impermeable layer wrapped around all other layers to prevent heat loss, water entry and to block the wind.[25]
19. Use a ground-insulating pad

Figure 2. Improvised wrap with internal vapor barrier



Heat source (if available)
Internal vapor barrier (plastic or reflective sheets)
Insulation (sleeping bag or blanket)
External vapor barrier (tarp or plastic)
External insulation (sleeping pad)

Figure 3. HPMK with improvised insulation (wool blanket).

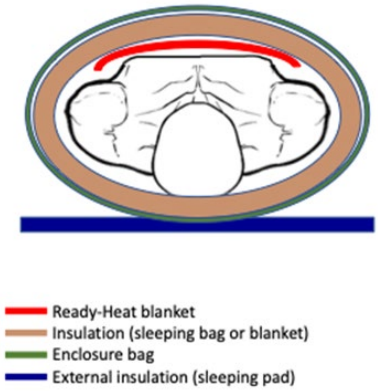


Table 1. Indications, contraindications, and other considerations for active warming.[5]

	Criteria	General Comments
Indications	· Moderate to severe trauma · Central nervous system trauma · Burn patients 20% TBSA with 2nd or 3rd degree. · Alerted level of consciousness; unresponsive; in cold environment. · Impaired shivering; in cold environment	Combat casualties with moderate to severe trauma should be managed with active heating inside a hypothermia wrap as soon as possible.
Contraindications	· None for TIH · Only when a casualty presents with signs and symptoms of hyperthermia (severe heat illness)	· There are no restrictions to use active warming inside a hypothermia wrap for TIH casualties. · It is contraindicated to use active warming for any casualty who presents with heat exhaustion or exertional heat stroke.
Safety	1st, 2nd, 3rd degree burns	· Never place any active heat source directly on skin. Follow manufacture directions for correct use of heating source.
Complications	Potential for enhanced muscle damage on an extremity distal to a tourniquet.	· Increased temperature of non-perfusion extremity distal to a tourniquet can cause further muscle damage. · Attempt to keep that part of the extremity from increasing temperature. · Do not pack extremity with a tourniquet in ice or snow.

~2-4 HOURS - TCCC, ERC, PCC

1. Continue and/or initiate above hypothermia interventions.

2. Upgrade hypothermia enclosure system to a well-insulated enclosure system using a hooded sleeping bag or other readily available insulation inside the enclosure bag/external vapor barrier shell. Best: Improvised hypothermia wrap with high-quality insulation with cold-rated sleeping bag combined with heat source, internal vapor barrier, outer impermeable enclosure.

3. Continue to use a battery-powered warming device to deliver blood at a flow rate up to 150 ml/min hr with a 38°C output temperature. (Table 2).

4. Convert to continuous temperature monitoring.
   - **Minimum**: Scheduled temperature measurement with vital sign evaluations.
   - **Better**: Continuous forehead dot monitoring.
   - **Best**: Continuous core temperature monitoring.

5. When using the HPMK Ready-Heat Blanket, perform frequent skin checks to monitor for contact burns.

~>6 HOURS - ERC, PCC

Continue and/or initiate the ruck/truck phases as detailed above. Replace Ready-Heat Blanket when using >10 hours.

ROLE 2 AND ROLE 3 PRIORITIES

- On patient arrival to the Role 2/3 facility, every effort must be made to prevent hypothermia; this should be a priority throughout resuscitative efforts and operative procedures. Control of ambient air temperature should be utilized to maintain a warm environment.
- Wet clothing and blankets should be removed immediately and a warming device applied if not done prior to arrival or if the device was damaged during transport.
- Use of warmed blood and blankets is indicated, where available, as well as forced air warming devices (Bair Hugger) as applicable.
- Continuous temperature monitoring is preferred, and temperatures should be documented on arrival to and discharge from the facility. A temperature sensing Foley catheter is a viable option to monitor temperature as well as the response to ongoing resuscitation efforts.
- If non-core temperature (oral, axillary, or tympanic) is outside of an expected range (<97F or >100F), use core temperature (rectal or esophageal) measurement for best accuracy.

EN- ROUTE CARE (ERC)

***NOTE**: Patient packaging with treatment for TIH is a core skill that should be deliberately planned and rehearsed prior to mission execution. A patient packaged for hypothermia prevention/treatment is difficult to access. Medical providers need to be cognizant of this fact and have a plan to monitor their patient's status as well as their prior medical interventions.*

- Ensure hypothermia management from the field is still in place and has not moved and or shifted during turnover. Ensure the hypothermia management system is covering the back and the system is protecting the patient from wind blowing over or under the casualty, especially in a rotary wing environment.
- Use of vehicle or aircraft Environmental Control Systems (ECS) should be used to create an ambient control temperature to allow passive room warming. ECS Systems can be unreliable, especially in rotary wing when power is limited. In preplanning, the ECS can be used to set a warm environment prior to or after receiving the casualty, to prevent drastic temperature loss.
- The use of continuous temperature monitoring should be conducted to establish and track warming trending.
- When moving patients in the maritime environment, doubling up of outer layering impermeable systems should be utilized to protect the patient from winds and sea spray.

FIELD "TRICKS OF THE TRADE" + ANECDOTAL "TROUBLE SHOOTING"

- Use RHB/active rewarming systems in maritime environment.
- On scene materials/clean trash bags or saran wrap may be helpful improvised insulation materials.

- Vehicle heating systems may help direct hot air to a patient in a field expedient Bair Hugger in certain platforms. This requires prior coordination and setup and is a non-standard equipment load.
- Use of thermal heat packs (crush packs, Ready Heat 1 Panel Blanket, MRE heater, even Foley bag in extremis) or body heat for fluid pre-warming (of most utility in Ruck-Truck-House phases when fluid warmers might be in short supply)
  Note: Do not place directly on skin to prevent thermal injury to patient.
- Expect issues with finger pulse-ox devices. If value shown does not correlate to patient presentation, remember to treat the patient, not the device. Taping heat pack over hand, but not in direct contact with the skin and device, may aid in accuracy/operation.
- In extreme cold weather (below -20°F), exhalation gas from intubated patients may cause ice to instantly form in the ET tube and vent tubing. Care should be taken to insulate all interventions while exposed to these conditions.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All trauma patients meeting DoDTR inclusion criteria with ISS>1.

INTENT (EXPECTED OUTCOMES)

- Temperature and route will be documented on all patients upon admission and discharge.
- Core temperatures are obtained on all patients with temperature <96 F and > 100° F.
- Warming measures and sustainment of core temperature > 96°.F are initiated on all patients.

PERFORMANCE/ADHERENCE MEASURES

- Temperature and route will be documented on all patients upon admission and discharge.
- Core temperatures are obtained on all patients with temperature <96 F and > 100° F.
- Warming measures and sustainment of core temperature > 96°.F are initiated on all patients.

DATA SOURCES

- Patient Record
- DoDTR

SYSTEM REPORTING & FREQUENCY

- The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.
- The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.
- For more information on metrics, email: dha.jbsa.healthcare-ops.list.jts-pips@health.mil

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

APPENDIX A – EQUIPMENT LIST

SECTION 1: PATIENT WARMING[1,2]

Table 1. Passive Rewarming Methods

- Level A: Evidence from multiple randomized trials or meta-analyses.
- Level B: Evidence from a single randomized trial or non-randomized studies.
- Level C: Expert opinion, case studies, or standards of care.
- NE = not effective; √ = mildly effective; √√ = moderately effective; √√√ = highly effective

	Prehospital	Reference	Rewarming	Level	Comments
Passive Rewarming Methods	Sleeping bag	Giesbrecht et al.[3]	√	B	Insufficient alone to prevent heat loss; works better with vapor barrier wrap with a when patient is shivering.
	Impermeable outer layer with sleeping bag insulation (burrito wrap)	Grissom et al.[4]	√√	B	Traditional passive rewarming approach in austere medicine courses. Works well with shivering patient in mild hypothermia to retain heat production and prevent body heat loss; active external heating source not required.
	Wool Blanket (WB)	Allen et al.[5]	NE	C	Prospective Randomized Study. No human volunteers. A single WB was least effective to prevent heat loss in fluid bag torso simulation.
	Space Blanket (SB)	Allen et al.[5]	NE to √	C	Prospective Randomized Study. No human volunteers: SB was placed over the simulation torso and tucked in. Was not as effective to prevent heat loss but better than the wool blanket.
	Human Remains Pouch (HRP)	Allen et al.[5]	√	C	Prospective Randomized Study. No human volunteers. The HRP did not maintain torso bladder temperature better than the wool blanket.
	HRS	Allen et al.[5]	√√√	C	Prospective Randomized Study. No human volunteers. New shell version was used as a passive bag. There was no statistical difference between the HRS and BB in heat loss between Gen 1 vs. Gen 2 HPMK.
	Hot Pocket (HP) (HRP, wool blanket, and space blanket)	Allen et al.[5]	√√√	C	Prospective Randomized Study. No human volunteers. The use of the HP system was very effective and one of two best passive methods of heat loss prevention, which performed the same as two of the three active heating methods tested at 120 minutes.
	Blizzard Blanket (BB)	Allen et al.[5]	√√√	C	Prospective Randomized Study. No human volunteers. The use of the BB alone was one of two best passive methods of heat loss prevention, which performed the same as two of the three active heating methods tested at 120 minutes.
	Vapor barrier + Hypothermia wrap	Thomassen et al.[6] Henriksson et al.[7] Henriksson et al.[8]	√√√	A	Strong evidence in favor of vapor barrier wrapped around human volunteers who were then placed inside hypothermia "burrito" wrap system. These three studies are the evidence for the recommendations for how to assemble an improvised a hypothermia enclosure system by Giesbrecht G.[9]

Table 2. Active Rewarming Methods

- **Level A**: Evidence from multiple randomized trials or meta-analyses.
- **Level B**: Evidence from a single randomized trial or non-randomized studies.
- **Level C**: Expert opinion, case studies, or standards of care
- NE = not effective; √ = mildly effective; √√ = moderately effective; √√√ = highly effective

Active Rewarming Methods	Prehospital	Reference	Rewarming	Level	Comments
	Small Chemical Packs	Co-author Consensus	NE	C	Small chemical heat packs used for hands are insufficient heat transfer to core or to prevent further heat loss. Better options available.
	Warm IV/IO fluids/blood products	Lehavi et al.[10] Haverkamp et al.[11]	NE	A	Do not infuse fluids less than 100°F (38°C). Fluids alone not effective for core temperature rewarming. Use fluids adjunctively with HPMK during MEDEVAC
	Body to body skin contact	Giesbrecht et al.[3] Hultzer et al.[12]	√	B	Suppresses shivering in victim with skin-to-skin contact; no more effective than shivering for mild accidental hypothermia; lack of evidence for any benefit in non-shivering hypothermic patient; loss of manpower.
	Hot water bottles	Co-author Consensus	√	C	Impractical. Insufficient to transfer heat to effect core temperature. Many bottles are needed; hot water replacement every 20 min.
	Walking	Giesbrecht et al.[13]	√√	B	Use to generate heat production in cold-stressed (>35°C (95°F)) victims with shivering intact, well protected from cold, wet and wind and with observer; use with caution – may cause afterdrop, 0.91°C core temperature decrease lasting nearly 30 minutes.
	Ready-Heat Blanket	Allen et al.[5]	√√	C	Prospective Randomized Study - Whole body heat blanket – 8 hours at 104 F (40°C); wrap torso and avoid direct placement on skin; use vapor barrier as outside layer.
	HeatPac	Giesbrecht et al.[13] Kulkarni et al.[14]	√√√	B	Effective to deliver heat and maintain thermal balance; costly; long-term experience in Scandinavian militaries and in research studies; resource dependent; uses charcoal as a consumable; potential carbon monoxide risk in low ventilation space; use outdoors only. Newer options available.
	HPMK	Allen et al.[5]	√√√	C	Prospective Randomized. Did not use human volunteers, but simulated torso with fluid bladder system. Effective outcome compared to all active heating systems studied. Committee on TCCC, JTS and DoD preferred system since 2006; outer vapor barrier garment and 10-hour (110°F) chemical blanket; low cost, weight, and size.; Effective system only for short-term use due to lack of insulation; patients will get cold <60 min use in cold environments per Dutta et al.[15]
	Improvised hypothermia wrap UAS	Dutta et al.[15]	√√√√	B	Randomized controlled study with human volunteers. The user-assembled and Doctor Down systems were most effective.
	Doctor Down Rescue Wrap (DD)	Dutta et al.[15]	√√√√	B	
	HPMK	Dutta et al.[15]	√√	B	Randomized control study with human volunteers. HPMK was least effective due to lack of insulation.

	MARSARS Hypothermia Stabilizer Bag (M)	Dutta et al.[15]	√√√	B	Randomized control study with human volunteers. These two systems were not as effective to retain thermal balance when compared to the DD and UAS systems.
	Wiggy's Victim Casualty Bag (W)	Dutta et al.[15]	√√√	B	
	Ready-Heat Blanket & PrimaLoft synthetic sleeping Bag hypothermia wrap	Phillips et al.[16]	√√√	C	Single case report with high efficiency to rewarm patient.

Other Patient Warming Devices

CAUTION: *Devices A-B should NOT be placed under the patient's back or directly on bare skin. Doing so may increase the likelihood of thermal burns or render the device inoperable.*

HAWK Warming Grid

- https://combatmedical.com/product/hawk-warming-grid/
- Air activated and heat adjustable. Can reseal individual cells for optimal performance.
- Conditions below 0F may require extended time (+15 minutes) to reach operating temperature
- 4-32 hours of operation

Ready-Heat Panel Blanket

- https://www.ready-heat.com/products/military/
- Air activated, NOT heat adjustable
- Conditions below 0F require extended time (+ 30 minutes) to reach operating temperature.
- Rendered inoperable by fluids and must ensure patient is dry prior to application and keep away from potential fluid sources.
- 8-10 hours of operation

Geratherm Mini Rescue II Hypothermia Kit

- www.rgmd.com
- Currently in the SOCOM Tribalco T-5 CASEVAC Kit

Chill Buster Blanket

Wiggy's or down sleeping bag

SECTION 2: FLUID WARMING[5]

Desirable Characteristics of a Resuscitation Fluid Warming Device

▪ Portable ▪ Lightweight (~2 lbs) ▪ Small dimensions (height, width, length) ▪ Ruggedized for field use ▪ Rapid start up <30 sec ▪ Water-resistant ▪ Low noise and light signature ▪ Long-life battery powered with easy replacement ▪ Battery duration for 4 units of whole blood at ≥100 to 150ml/min	▪ Rapid battery recharge duration <100 min ▪ Recharger unit for two to three batteries ▪ Optional IV tubing lengths ▪ Flight approved (airworthy) ▪ Functions in hypo/hyperbaric environments ▪ Operating conditions for battlefield temperature ▪ (-10°C to 45°C) and humidity (5 to 95% rh) ▪ Fluid and blood products output temperature at least 38°C at ≥100 to 150ml/min (4°C starting temperature) ▪ Reusable warming device

List of warming devices available on the market.

- **Level A**: Evidence from multiple randomized trials or meta-analyses.
- **Level B**: Evidence from a single randomized trial or non-randomized studies.
- **Level C**: Expert opinion, case studies, or standards of care.

Abbreviations: √, mildly effective; √√, moderately effective; √√√, highly effective

Warming Device	FDA Approval	Flight Approved	Rewarming Efficacy >100mL/Min	Level	Reference	Comments
Belmont Buddy Lite	Yes	Yes	√	A	Bruells et al.[17] Kim et al.[18] Lehavi et al.[10] Milligan et al.[19] Weatherall et al.[20]	Higher administration rates will cause the cartridge to pop out of the locking block.
Thermal Angel	Yes	Yes	√	A	Weatherall et al.[21]	Higher administration rates drastically drop the end output temperature. At colder input temperatures, the Thermal Angel administration rate drops.
enFlow	Yes	Yes	√	A	Bruells et al.[17] Kim et al.[18] Lehavi et al.[10] Zoremba et al.[21]	Device performs best when working with warmer fluids, as cited in Kim et al. study. *****DEVICE RECALLED due to aluminum elution from warming cartridge*****
QinFlow Warrior	Yes	Yes	√√√	A	Lehavi et al.[10]	Performed the best in comparison to the other warmers with colder input temperatures.
QinFlow Warrior Lite	Yes	Yes	√√√	C	N/A Peered Research	Same warming cartridge as QinFlow Warrior.
MEQu M Warmer	No	Yes	√√√	A	Blakeman et al.[22] Weatherall et al.[20]	NATO approved, awaiting FDA approval, performed best in side-by-side comparison of the Buddy Lite, Buddy Liter, and Thermal Angel with packed red blood cells
Lifewarmer Quantum*	Yes	Yes	√√√	C	N/A Peered Research	Not currently peer reviewed. **SOCOM funded device.*

SECTION 3: TEMPERATURE MONITORING

Temperature Monitoring Devices

- Temperature sensing Foley
- (Forehead) temperature sensing 'dots'
- DataTherm(R)II Continuous Temperature Monitor - in the SOCOM Tribalco T-5 Cardiac Ki
- Propaq MD
  - Airworthiness approved

    - BATDOK (Battlefield Assisted Trauma Distributed Observation Kit) enabled
    - Several different options available for real-time temperature monitoring
- Philips Tempus Pro - Airworthiness approved
- Welch Allyn SureTemp - Airworthiness approved
- 3M Bair Hugger Temperature Monitoring System[23] - Portable device still under development, but may have applicability in the trauma setting

APPENDIX B: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command-requested, unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

CRITICAL CARE AIR TRANSPORT CLINICAL PRACTICE GUIDELINE

THE I-STAT PORTABLE BLOOD ANALYZER IN AUSTERE LOCATIONS (CPG ID:47)

The goal of this clinical practice guideline (CPG) is to present the proper use and maintenance of use of the i-STAT portable blood analyzer, with a focus on the en-route care environment. The series is developed by the Center for Sustainment of Trauma and Readiness Skills, University of Cincinnati Medical Center.

Major updates

1. The procedure for receiving a new shipment of cartridges has been added.
2. The method for correctly obtaining a blood specimen, to include criteria for specimen rejection, has been included.
3. An appendix for how to prepare a cartridge for analysis has been developed.
4. An appendix for running a control and an external simulator has been inserted.

Goal

This guideline outlines the expectations and instructions for maintenance, calibration, quality control, and use of the i-STAT portable blood analyzer. Updates include how to mitigate the negative impact of harsh environmental conditions found in deployment on the equipment and analyzer results.

Background

Point-of-care (POC) testing is defined as a pathology or laboratory test that is performed at the site of clinical interaction allowing immediate decision regarding treatment.[1] Because POC tests are performed in a non-laboratory setting, they are designed to be as simple as possible and produce reliable results when used by non-laboratory health-care professionals.[2] In this sense, POC testing is ideal for the En-Route Critical Care (ERCC) environment, however, austere ERCC conditions can affect the POC test results. One of most important environmental factors that medics must always be cognizant of are extremes in ambient temperature; exposure to extreme temperatures can render results inaccurate.

Critical Care Air Transport Teams (CCATTs) use the i-STAT (Abbott Point of Care, Princeton, NJ, USA) as their POC device (Figure 1).[3] CCATT must therefore understand how to use the equipment, be able to troubleshoot and calibrate the analyzer, and also provide quality assurance with controls and simulators (the function of controls and simulators will be defined below). In addition, teams must be aware of the specific drugs and environmental conditions that alter test accuracy. Finally, teams are also responsible for protecting POC testing equipment from the elements.

Figure 1. i-STAT Analyzer

The i-STAT analyzer can measure multiple different lab values: cardiac troponin I, electrolytes, blood gas, urea, creatinine, glucose, ionized calcium, and international normalized ratio (INR).

Test results from the i-STAT are generally available in 10 minutes or less. The results displayed on the screen depend on the type of cartridge inserted into the analyzer.

The cartridges that are typically stocked for use by CCATT are the CHEM8+, CG8+, EG7+, and CG4+. Cartridges are each loaded with a sample of the patient's blood and inserted into the bottom port of the analyzer for analysis.

The **CG8+ cartridge** (Figure 2) measures glucose, sodium, potassium, ionized calcium, hemoglobin, and hematocrit. The blue arrow just to the right of "CG8+" defines the fill mark when blood is loaded into the cartridge; this indicates the volume of blood necessary to perform the test.

The **EG7 cartridge** measures sodium, potassium, ionized calcium, hemoglobin, hematocrit, pH, $PaCO_2$, PaO_2, TCO_2, HCO_3, base excess, SO_2.

The **CHEM8+ cartridge** (Figure 3) measures creatinine, Blood Urea Nitrogen (BUN), glucose, ionized calcium, anion gap, TCO_2, chloride, potassium, and sodium. The fill mark is at the beginning of the blue segment.

The **CG4+ cartridge** measures lactate, pH, $PaCO_2$, PaO_2, TCO_2, HCO_3, base excess, SO_2.

The quality controls for the i-STAT system are simulators and controls. There are two types of simulators for the i-STAT: internal and external. Internal simulators are built into the analyzer and external simulators (Figure 4) must be inserted into the analyzer in the same port that receives the cartridge. Both types of simulators mimic the signals that a cartridge, loaded with blood, would send to the analyzer; simulators validate the analyzer. Controls are liquids that are injected into the cartridge (instead of blood); the cartridge is then inserted into the analyzer and run to validate the cartridge. CCATT members are tasked to perform these quality checks to ensure lab tests are accurate.

Figure 2. CG8+ cartridge.

Figure 3. CHEM8+ cartridge

Figure 4. External simulator

Procedure for Handling New Cartridge or Control Shipments

Cartridges must be kept refrigerated to maintain their integrity and reliability. Therefore, upon receipt, open the box marked "Refrigerate upon Arrival." Next, identify the card with the temperature strip attached and read it. Once it is exposed to room temperature the reading will begin to change. Follow instructions on card and if the reading is found to be unacceptable, contact technical support.

Record the temperature reading on the "Receipt of New Cartridges" Log.

If the temperature strip reading is acceptable, perform a test of one cartridge from each box with the liquid control; this validates the remaining cartridges within each box. If you receive multiple boxes with

the same cartridge lot number you only have to run the test once instead of running controls for each box. A similar procedure should be used for shipments of controls.

Storage: Procedures for Cartridges, Controls and the Analyzer

Cartridges: The main supply of cartridges should be kept refrigerated at 2—8°C (35—46°F). In this state, they may be used until the date shown on the cartridge pack or box. Do not allow the cartridges to freeze. Cartridges may also be stored at room temperature (18-30°C or 64-86°F) for the time frame defined on the cartridge box. For example, CG8+ cartridges may be stored at room temperature for up to 2 weeks; then they must be discarded. Cartridges should not be returned to the refrigerator once they have been warmed to room temperature, and they should not be exposed to temperatures above 30°C (86°F). If a cartridge is removed from the refrigerator, then the labeled expiration date should be crossed out and the temperature expiration date should be written on the cartridge package.

Controls: Blood gas, electrolyte, and chemistry controls should be stored at 2—8°C (35—46°F). They may also be stored at room temperature (18 to 30 °C or 64 to 86 °F), but only for up to 5 days.

Analyzer: The i-STAT analyzer (and accessories) should be stored in the hard plastic case provided in the allowance standard. The device should be protected from extremes of temperature as much as possible. The optimal operating temperature range is 16 to 30 ºC.

Electronic Simulator: Store at room temperature and protect contact pads from contamination by making sure the blue plastic cap (Figure 4) covers the contact pads when stored in its protective case after use.

Deployment Considerations

One challenge for POC testing in the deployed setting is keeping the equipment within the proper temperature range.

- Cartridges used for a mission may be placed in the CCATT refrigerator bag to avoid temperature exposures above 30°C (86°F). Another option is to hand carry the i-STAT cartridges rather than leave them in the gear set. Do not leave the i-STAT cartridges exposed to direct sunlight and maximize use of climate-controlled environments (e.g., flight-line vehicles) to moderate temperature extremes.
- Optimal operating temperature for the i-STAT analyzer is 16—30 ºC (61—86ºF). If the device is either too hot or too cold at power-up, the following error message will be displayed on the screen: Temperature Out of Range. For a cold device, find a warm area on the aircraft or truck or place the analyzer in your flight suit to warm up. When the device is too hot, rest it on top of an ice pack and protect it from getting wet with a piece of plastic or a Chux pad. Typically only 5 minutes is needed to reduce the temperature to an acceptable level. If an aircraft is pre-positioned with equipment to minimize response time for “wheels-up,” the i-STAT may become too hot and not function.
- If a cartridge is used beyond its temperature expiration date, or if a cartridge is used despite having been exposed to a temperature beyond 30°C (86°F), then annotate this on the 3899L (next to the lab result). It is left the provider’s discretion whether to use the results in clinical decisions.

Blood Sample Collection: Procedure for Arterial and Venous Draws

For cartridge testing of blood gases, electrolytes, chemistries, and hematocrits, draw the patient's blood as described below.

Blood Draw

Completely fill a plain syringe, blood gas heparinized syringe (in the CCATT allowance standard), or a syringe with the minimum volume of heparin to prevent clotting (10 U/mL of blood). Mix a heparinized syringe by rolling it between the palms for at least 5 seconds in two directions, then invert the syringe repeatedly for at least 5 seconds. For best results, test the blood immediately. For samples measuring pH, PCO_2, PO_2, TCO^2, and ionized calcium, sample processing within 10 minutes of blood draw is acceptable; other analytes can be processed within 30 minutes of blood draw if a heparinized syringe was used. If a tourniquet is used for a venous stick, do not leave it on for more than 1 minute; do not draw blood proximal to an IV site.

Criteria for Specimen Rejection

1. There is evidence of specimen clotting.
2. Specimens were collected in vacuum tubes with anticoagulants other than lithium or sodium heparin.
3. Syringe for pH, PCO_2, PO_2, or TCO_2 has air bubbles in sample. An air bubble stuck only on the plunger will not affect the results.

Precautions: Avoid the Following Circumstances

- Drawing a specimen from an arm with an IV.
- Stasis (tourniquet left on longer than 1 minute before venipuncture).
- Extra muscle activity (fist pumping).
- Hemolysis (alcohol left over puncture site or a traumatic draw).
- Time delays before filling cartridge.
- Exposing the sample to air when measuring pH, PCO_2, PO_2, or TCO_2.

Cartridge Preparation for Loading Blood Sample

- Prior to using a cartridge, it must be removed from refrigerated storage and kept at room temperature in its protective pouch for at least 5 minutes.
- An entire box of cartridges must be kept at room temperature for 1 hour before a cartridge from the box can be used. Avoid condensation from forming on a cold cartridge as it may prevent proper contact with the analyzer.
- The process for loading the cartridge with blood is detailed in Appendix A.

Quality Assurance

Electronic Simulators

- The i-STAT analyzer has both an internal and external simulator to perform quality checks. Simulators mimic the signals that would be sent from a cartridge charged with blood to validate whether the analyzer is functioning properly.
- The analyzer runs a comprehensive check with the internal simulator each time a patient's blood sample is tested.
- The external simulator needs to be plugged into the analyzer where a cartridge is attached. **The external electronic simulator should be run when indicated by the i-STAT device or every 8 hours while in use. If mission is over 8 hours, it is recommended to run the external simulator prior to the mission and then again if the mission is over 8 hours.** The testing procedure takes approximately 120 seconds. Appendix B details how to run an external simulator.
- **Any analyzer that fails an electronic simulator check twice (internal or external) should be removed from service and turned in for maintenance.**
- The i-STAT analyzer is programmed to lock out if the internal or external simulator does not pass the quality control.

Liquid Controls

- Liquid controls, which are injected into cartridges, verify the cartridges are producing accurate results and should be used each time a new batch of cartridges is opened. Controls may also be ran if there is concern that a group of cartridges was placed in an environment outside of the storage guidelines – for example, in a place with an ambient temperature above 30°C (86°F). In particular, Level 1, 2, and 3 controls for blood gas/electrolyte/metabolite cartridges are formulated solutions that represent 3 clinically relevant levels of known pH and with known concentrations of sodium, potassium, chloride, ionized calcium, PCO_2, PO_2, TCO_2, glucose, lactate, BUN, and creatinine. Level 1 and 3 controls are typically stocked for deployed CCATTs.

  Note: *Hemoglobin is validated with another type of control (RNA Medical® Hematocrit Calibration Verification) that is not typically stocked for CCATTs.*
- Liquid controls do not need to be run if cartridges are obtained from a military treatment facility (MTF) lab that complies with this Clinical Practice Guideline (CPG). One should not assume, however, that the MTF is running controls with their cartridges.
- Consult the manufacturer's documentation if you plan to use cartridges not listed in this CPG because you will need to obtain the proper controls and run them prior to use, as well as update the software through your local Biomedical Equipment shop.
- Appendix C describes how to run controls.

Internal quality check

If stars (***) are displayed instead of a lab result, it means that a test failed the internal quality checks. All other reported results are accurate as long as the sample integrity is not in question. If this occurs, one can remix the tube of blood and repeat the test using a new cartridge. If the result fails to display

again, draw a fresh blood sample and repeat the test. If the result is still not displayed, consider turning the device in for maintenance or call technical support.

Medications That Can Affect i-Stat Results

- For patients administered propofol or thiopental sodium, i-STAT recommends the use of CG4+, CG8+, EG6+, and EG7+ cartridges, which are free from clinically significant interference at all relevant therapeutic doses. i-STAT does not recommend the use of EC8+ cartridges for patients receiving propofol or thiopental sodium.
- Acetaminophen and creatine can increase creatinine measurements by 0.20—0.25 mg/dl.

Documentation

- Document that liquid controls were used to verify a new box of cartridges on a log or on the box containing the cartridges.
- Document in the 3899L *Patient Movement Record Enroute Critical Care* form if a used cartridge was not stored or quality checked correctly: (1) if controls were not run for a new box of cartridges, and the cartridge was used, (2) if an expired cartridge was used, and (3) if a cartridge was used but was placed in an environment not consistent with proper storage (e.g., temperature above 30°C/86°F).

Practical Advice to Optimize Use of the i-STAT in the Deployed Setting

- Seek arrangements permitting you to obtain extra i-STAT cartridges from MTFs if your supply chain is limited, however, they are in no way obligated to do so. If the deployed location does not have a refrigerator, it may also be possible to drop off your main store of cartridges at the MTF for temperature-controlled storage and the running of controls. Obtaining cartridges from an MTF laboratory will eliminate the need to monitor storage temperature. Some laboratories, however, do not use i-STAT, so they may only be able to store your controls and cartridges; you will still be responsible for ensuring that the liquid controls are completed.
- Consider comparing the i-STAT results with MTF derived values:
- When circumstances permit, teams are advised to perform one i-STAT test while MTF personnel simultaneously measure the same parameters on a patient.
- If the results are similar, it adds some certainty to the accuracy of the i-STAT and cartridge lot currently in use.
- Discordant results suggest a problem with the analyzer or cartridges and should prompt further investigation; the team should consider turning the device in for maintenance.
- **There is no scientific basis for determining the direction and magnitude of difference between the i-STAT and MTF lab and then using that value as a correction factor to adjust results.** There is no reason to believe that the difference in values will be in the same direction or of the same magnitude for subsequent measurements.

Software Updates

- The sensors in the i-STAT cartridges are standardized against plasma methods used by major laboratory systems. The i-STAT is programed with CLEW software, the coefficients of which are determined by comparing the i-STAT results to this standardization process. Due to possible changes in the manufacturing process, the CLEW software requires recalibration to avoid drift from the lab values produced by the major laboratory systems. This is why software updates are mandated twice a year.
- The i-STAT analyzer will not function with expired software. A warning will appear on the screen 15 days before the software expires.
- The i-STAT can be updated using a desktop computer or another i-STAT with current software (Appendix D).
  - This method may be problematic for deployed personnel due to regulations preventing attachment of devices to government computers.
  - If this method is approved by command, the software can be downloaded from the internet.
  - Navigate directly to http://www.abbottpointofcare.com/Customer-Info-Center.aspx.
  - Registration using a military email address will be required.
- The i-STAT can be updated using a second i-STAT with current software. This method may be easier in the deployed setting since it avoids the issue of having to attach a device to a government computer and does not require the internet. The second device may be obtained from another CCATT or an MTF. A step-by-step instruction set is presented in Appendix D.
- **It is recommended that deployed personnel coordinate with a nearby MTF or contact a servicing biomedical maintenance shop as needed for assistance with software updates.**

Visual Overview of Properly Stored Equipment

Abbott Point of Care Customer Support

- Assistance from Abbott website.
  1. Go to https://www.pointofcare.abbott/us/en/home.
  2. Choose Support from the horizontal menu at the top of the page.
  3. You will need to create an account and/or log in.
- Email techsvc@apoc.abbott.com
- Call 1-800-284-0702.

Fixed (Expected Clinical Proficiency)

CCATT members are expected to be able to perform the following tasks:

1. Receive cartridge and control shipments.
2. Obtain blood specimens correctly and identify inadequate samples.
3. Perform quality controls for the i-STAT system.
4. Process blood samples.
5. Store the equipment correctly.
6. Mitigate environmental conditions (such as temperature) that can affect equipment and results.

Appendix A: Procedure for Preparing and Running an i-STAT Sample

Step 1: Verify the type of cartridge to use and check the expiration date. Ensure the cartridge is at room temperature.

Step 2: Power on the analyzer (bottom right button). Select option 2 to run a new lab test. You will be prompted to enter you user ID (use the last 4 digits of your SSN); hit ENTER. You will have to reenter your ID for confirmation. Then enter patient ID (last 4 of the patient's SSN, if available); hit enter. Repeat for confirmation.

Step 3: Scan the barcode on the cartridge packaging, (Figure A1); this defines for the analyzer which cartridge type is being run and it also checks the expiration date. Simply press and hold the SCAN button and point at the bar code on the cartridge packaging (Figure A1). The screen will then instruct you to insert a cartridge. You are ready to prepare the cartridge.

Step 4: Collect the blood sample. (Method is defined in *Blood Sample Collection: Procedure for Arterial and Venous Draw*).

Step 5: Tear open cartridge package and remove the cartridge, only touching edges (Figure A2). Touching the metal contacts on the top of the cartridge may affect results.

Step 6: Before injecting blood into the sample well, ensure there are no bubbles in the sample (these can affect CO_2 results).

Step 7: Fill cartridge to the appropriate fill line (Figure A3). The Chem8+ and CG4+ cartridges have fill lines that are at the beginning of the blue segment (Figure 3); CG7 and CG8+ cartridges have a blue arrow (Figure 2). Use the best flat surface on the aircraft for injection. The sample well should be about halfway full

Step 8: Seal the cartridge's sample well by rotating the well's cover and snapping it closed (Figure A4) ***DO NOT press directly over the sample port****, as blood may be pressurized, potentially bursting/failing the cartridge* (Figure A5). Apply pressure only at the edge of cap when sealing

Step 9: Insert the cartridge into the analyzer; results will display in 2–4 minutes. Toggle arrow buttons to view different pages of results.

Figure A1. Scanning cartridge bar code

Figure A2. Proper cartridge handling

Figure A3 Loading cartridge sample well with blood

Figure A4. Rotating cover

Figure A5. Sealing the cartridge

Appendix B: Procedure for Running the External Simulator

The external simulator (Figure 4) mimics the signals that would be sent from a cartridge to validate whether the analyzer is functioning properly. In particular, it simulates two levels of electrical signals that stress the analyzer's signal detection function both below and above measurement ranges. It provides an independent check on the ability of the analyzer to take accurate and sensitive measurements of voltage, current, and resistance from the cartridge. An analyzer will PASS or FAIL this test depending on whether or not it measures these signals within specified limits. ***The electronic simulator will fail if high relative humidity interferes with the measurements.***

If the analyzer and simulator have been stored separately in areas where the ambient temperature differs by more than 3°C (5°F), allow the simulator and analyzer to stand in the same place for 30 minutes before inserting the simulator into the analyzer. ***Handle the simulator as little as possible to maintain its thermal uniformity and stability.***

Procedure for running the external simulator:

Step 1: Power on the analyzer (bottom right button).

Step 2: Ignore options 1 or 2 that appear on the screen and press the Menu button, then select Option 3 for Quality Test.

Step 3: A sub-menu appears; select Option 4 for Simulator.

Step 4: Scan the external simulator's barcode into the analyzer by pressing and holding the Scan button. Another option is to manually enter the number associated with the bar code.

Step 5: Insert the external simulator into the same port where cartridges are inserted with the "I" facing up (Figure 4); do not touch the contact pads. Cartridge Locked will be displayed, indicating that the simulator should NOT be removed. An attempt to forcibly remove the simulator during this cycle may damage the analyzer. It will take about 60 seconds for the test to run. PASS or FAIL will show on the screen.

- If PASS is displayed, remove the simulator ONLY after the *Cartridge Locked* message disappears from the screen.
- If FAIL is displayed, repeat the procedure with the same external simulator. If PASS displays after the second attempt, the analyzer may be used. If FAIL is displayed, repeat the procedure with a second analyzer; the analyzer may be used if PASS is displayed. If FAIL is displayed, repeat the procedure with the same, second simulator. The analyzer may be used if PASS is displayed. For a second FAIL display (using a second external simulator), the analyzer cannot be used and should be turned over to maintenance.

Appendix C: Procedure for Running Controls

Level 1, 2, and 3 controls for blood gas/electrolyte/metabolite cartridges are formulated at three clinically relevant levels with known pH and with known concentrations of sodium, potassium, chloride, ionized calcium, PCO_2, PO_2, TCO_2, glucose, lactate, BUN/urea, and creatinine. Level 1 and 3 controls are typical stocked for deployed CCATTs.

Verifying hematocrit measurements, however, requires another type of control: the RNA Medical® Hematocrit Calibration Verification Controls. Levels 1, 3, and 5 should be run on the following cartridges: E3+, EC4+, 6+, EC8+, EG6+, EG7+, CG8+, and CHEM8+. This control is NOT typically stocked for CCATTs downrange.

Liquid controls used in a cartridge that measures oxygen concentration must stand at room temperature for a minimum of 4 hours before use; controls for other analytes only need to equilibrate at room temperature for 30 minutes. The analyzer should also stand at room temperature for 30 minutes.

Procedure for running a control:

Step 1: Put on gloves.

Step 2: Press the On button.

Step 3: Press the Menu key; then press 3 to select Quality Tests.

Step 4: Press 1 to select Control.

Step 5: You will be prompted to scan or manually enter the Operator ID and Control Number. It may be convenient to enter 1 as the operator ID for a level 1 control and 3 for a level 3 control; this may make it easier when comparing the results to the *Value Assignment Sheet*.

Step 6: Press Scan to scan the barcode cartridge lot number.

Figure C1. Level 1 and 3 ampules

Step 7: Remove the cartridge from the package, taking care to handle it only along the edges, otherwise the results may be affected. Place the cartridge on a flat surface.

Step 8: Shake the control ampule (Figure C1) hard 15–20 times (for at least 10 seconds) and then tap the ampule to restore the liquid to the bottom of the ampule.

Step 9: Open the ampule by snapping off the tip. Protect fingers with gauze or use an ampule breaker.

Step 10: Immediately transfer control to syringe as follows: use a clean 3 mL syringe. Replace attached needle with a 19-gauge blunt tip needle, if available, for safety. Avoid drawing air bubbles into the syringe.

Step 11: Immediately expel 3 drops of control on a pad/gauze and then fill cartridge to the fill line and seal the cartridge (see Appendix A for details). Aqueous-based solutions such as controls do not have the buffering capabilities of whole blood; therefore, once opened, they must be immediately transferred to the cartridge (unlike with a patient's sample).

Step 12: Do not use the solution left in a syringe or ampule for additional testing of cartridges that contain sensors for ionized calcium, pH, PCO_2, or PO_2; a new ampule must be used.

Step 13: Insert cartridge into the analyzer; do not remove until *Do Not Remove Cartridge – Cartridge Locked* message is gone.

Step 14: Control Evaluation. Compare the results to the *Value Assignment Sheet*. If any result is out of range, repeat the control testing with a fresh ampule and syringe. If any result is still out or range, do not use any of the cartridges from this lot. *Value Assignment Sheets* are obtained from the Abbott Point of Care website (http://www.abbottpointofcare.com/Customer-Info-Center/Value-Assignment-Sheets.aspx). You will need to know the CLEW version on your device and the lot number of the control solution you used.

Note: *Correction of PO2 value is required when running controls at locations more than 1000 feet above sea level. Use the barometric pressure reading from the i-STAT status screen and the following formulas:*

- For PO2 values < 150 mmHg: for every decrease of 15 mmHg in barometric pressure from 760 mmHg, add 1 mmHg to observed PO_2 value.
- For PO2 values > 150 mmHg for every decrease of 35 mmHg in barometric pressure from 760 mmHg, add 1 mmHg to observed PO_2 value.

Appendix D: Updating i-STAT CLEW Software using another i-STAT Device

We recommend that biomedical maintenance preform this procedure, if possible.

The sensors in the i-STAT cartridges are standardized against plasma methods used by major laboratory systems. The i-STAT is programed with CLEW software, the coefficients of which are determined by this standardization process. Due to possible changes in the manufacturing process, the CLEW software requires recalibration to avoid drift from major laboratory systems. This is why software updates are mandated to occur twice a year.

Step 1: Be certain both i-STAT devices have at least 7.5 volts of battery power remaining.

Step 2: Turn the power off on the receiving device. The power on the receiving device will remain off for the entire procedure.

Step 3: Place both devices on a flat surface with the infrared windows aligned approximately 1 foot apart.

Step 4: Turn on the sending device, press Menu, and select option 7 for Utility.

Step 5: Press ENT when prompted for a password.

Step 6: In the utility menu press 1 for Send Software.

Step 7: Press 1 for JAMS###/A##.
***Note**: the numbers have been replaced with # in this example; they will change with each software update.*

Step 8: When the sending device displays *Waiting to Send*, start sliding the receiving device towards the sending device with the infrared windows aligned until the sending device displays *Sending*. Do not lift it off the flat surface.

Step 9: Wait until the sending device returns to the utility menu and displays *Last send successful* before moving devices.

Step 10: Run the external electronic simulator on the receiving device to verify successful software update.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Infection Prevention in Combat-related Injuries (CPG ID:24)

Provides rationale and guidance for the prevention of infection after combat-related injuries.

SUMMARY OF CHANGES

1. New references have been added based on new data from the *Trauma Infectious Disease Outcomes Study* supporting previous recommendations to limit gram negative therapy for prophylaxis of extremity wounds.
2. The duration of antibiotics for open fractures has been curtailed to only the first 24 hours and re-dosing with subsequent irrigation and debridement.
3. Clarification had been added to describe the cohorting of patients. Long term patients (>72 hours) had been clarified to mean host nation patients; short term (<72 hours) has been clarified to mean U.S. personnel.
4. Antimicrobial stewardship recommendations have been expanded to include the recommendation for facilities responsible for trauma care to monitor adherence to antimicrobial prophylaxis regimens.
5. Reach back information has been updated to include the ADvanced VIrtual Support for OpeRational forces (AD.VI.S.OR) network and to the updated Army Infection Control email address.
6. Vancomycin dosing has been updated to reflect weight-based dosing and clindamycin dosing has been simplified.
7. A tetanus prophylaxis appendix has been added.

BACKGROUND

Infection has been a complication of war wounds throughout history. Infection prevention and control techniques in combat injuries, first widely practiced by Florence Nightingale in the Crimean War, have significantly advanced the care of the injured patient. The battlefield poses unique challenges in care for combat-related injuries. These include multiple patient transfers between hospitals and teams, the austere environment of theater medical care, and the difficulties arising during long distance aeromedical evacuation.[1-3] Infections are frequent complications of combat casualties and are characterized by multi-drug resistant organisms (MDROs). MDROs are predominantly acquired through nosocomial transmission in the chain of tactical combat casualty care.[4-5] These MDROs have been shown to originate from colonization of host nation patients which sets the stage for a more complicated healthcare environment. Infection prevention and control practices must be able to effectively adapt to these challenges and support the prevention and spread of infection by implementation of early and repetitive surgical wound care.

NOTE: *Related Clinical Practice Guidelines (CPGs) published by the Joint Trauma System (JTS): Ventilator-Associated Pneumonia; Blunt Abdominal Trauma Splenectomy Post-Splenectomy Vaccination; Invasive Fungal Infection in War Wounds; War Wounds: Debridement and Irrigation; Acute Traumatic Wound Management in the Prolonged Field Care Setting. CPGs are posted at https://jts.health.mil/index.cfm/PI_CPGs/cpgs.*

STANDARD PRECAUTIONS

These standard precautions apply to all patients, regardless of suspected or confirmed infectious status. The application of standard precautions during patient care is determined by the nature of the interaction between the healthcare worker and the patient, in addition to the extent of anticipated blood, body fluid or pathogen exposure.[6] These include but are not limited to the following.

- **Hand washing**: The World Health Organization's "five moments of hand hygiene" include:
  1. use of soap and water or alcohol-based sanitizer before patient contact;
  2. before aseptic tasks;
  3. after body fluid exposure risk;
  4. after patient contact; and
  5. after contact with patient surroundings, even if gloves were worn.[7]

  The gold standard to ensure adherence is direct observation which allows for immediate corrective feedback.[8]
- **Gloves**: Use to prevent contamination of hands when anticipating direct contact with non-intact skin, mucous membranes and blood or body fluids (e.g., dressing changes, starting IVs).
- **Gowns**: Isolation gowns are specified by standard and transmission-based precautions to protect the healthcare worker's arms and exposed body areas and prevent contamination of clothing with blood, body fluids, and other potentially infectious material (e.g., changing dressings or open wounds). Gowns are always used in conjunction with gloves.
- **Masks**: Masks protect healthcare workers from contact with infectious material originating from patients. They are also used to protect the patient when performing sterile techniques to protect patients from exposure to infectious agents carried in a healthcare workers' mouth or nose.
- **Goggles or Face Shields**: Use is based on anticipated exposure. Personal eyeglasses and contact lenses are not considered adequate eye protection.

Emphasize basic infection prevention control efforts (for example, hand hygiene, cohorting, transmission-based isolation) to prevent spread from other hospitalized patients and to decrease antibiotic pressure selecting for resistant organisms.

TRANSMISSION-BASED PRECAUTIONS

Transmission-based precautions covers droplets, airborne and physical contact. For this CPG, we will only describe the use of contact precautions for epidemiologically important organisms to include Clostridium difficile (C. difficile).

- **Cohorting**: Cluster host nation patients (who are not eligible to evacuate from theater) and U.S. and coalition patients (who are eligible for evacuation from theater) and separate when possible to reduce the risk of cross-contamination with MDROs.
- **Contact Precautions**: Gloves and gowns should be worn with all patients suspected or known to have MDRO colonization or infection with C. difficile- infection (CDI) and immediately placed

into contact precautions.[8] Refer to Appendix A of the 2007 Isolation Guidelines published by the Centers for Disease Control and Prevention (CDC) for a list of all diseases requiring contact precautions.[6]

NOTE: *U.S. personnel with skin and soft tissue infections presenting with abscess or furuncles should be assumed to have community-associated Methicillin-Resistant Staphylococcus Aureus (MRSA).*

- **Skin care**: Intensive care unit (ICU) patients should undergo daily bathing with topical chlorhexidine gluconate (CHG). CHG-impregnated wipes are available commercially. CHG has broad activity against gram-positive and gram-negative bacteria, facultative anaerobes and aerobes. Daily bathing of ICU patients has shown a reduction of infections with vancomycin-resistant enterococci (VRE) and methicillin-resistant staphylococcus aureus (MRSA). Daily bathing with CHG washcloths significantly reduces the risk of acquisition of MDROs.[9-11] See Appendix E: Antiseptic Body Cleaning.[11]

ANTIMICROBIAL STEWARDSHIP

- Antimicrobial drug usage contributes to the development of multidrug-resistant organisms. Use of overly broad antibiotics for combat trauma prophylaxis has resulted in an increased risk of MDRO infection without improvement in long-term clinical outcomes such as number of surgical procedures, length of hospitalization, or osteomyelitis.[12,13]
- All facilities should avoid unnecessary empiric use of broad spectrum antibiotics.
- When available, use local antibiogram to guide empiric therapy.
- Limit duration of antibiotic therapy. Several well-controlled studies have shown benefit to shorter courses of antibiotic therapy for common infectious problems (for example, pneumonia.). Prolonged duration of prophylaxis has not been shown to decrease long term rates of infections in retrospective study of 1,044 patients with combat-related open fractures.[12] The shortest course of post-injury antimicrobial therapy should be used.
- Appendix B: Post-Injury Antimicrobial Agent Selection and Duration describes antimicrobial prophylaxis regimens and proposed durations for combat wounded personnel.

ADHERENCE TO ANTIMICROBIAL PROPHYLAXIS

All facilities responsible for trauma care should monitor adherence to antimicrobial prophylaxis regimens.[14] Special situation: care of combat injured secondary to suicide bomber/blast injury

Blast injuries, especially those related to suicide bomber attacks, present a unique bloodborne pathogen risk if an impaled body part is introduced into the trauma patient. There have been reported cases of Hepatitis B virus (HBV)-positive impaled bone fragments recovered from suicide bomber victims in Israel.[15,16] This prompted the Israeli Ministry to provide post-exposure HBV vaccination as a practice. Since the initiation of the vaccine, HBV impaled fragments have been reported but no disease transmission.[17]

Prior to deployment, U.S. forces are required to receive a three-dose vaccine series, but 5-14% of vaccinated patients fail to achieve immunity (anti HBs <10 mlU/ml) which places them at increased risk

of transmission.[18,19] Thus we recommend attempting to verify anti-HBV status in those who are combat injured secondary to a suicide bomber and provide HBV immunoglobulin (HBIG) and HBV vaccine for those incompletely vaccinated with unknown titers or anti-HBs<10 mlU/ml. Recombinant Hepatitis B vaccine may be considered in those who have failed to respond to conventional Hepatitis B vaccine.

The risk of transmission for human immunodeficiency virus (HIV) is considered very low after blast injury and generally warrants no action.[17] However, in the case of penetrating blast injury in a highly endemic region, expert teleconsultation should be obtained to discuss case specifics. Specific recommendations can be obtained via email (usarmy.jbsa.medcom-rhc-c.list.amedd-ic-consult@health.mil) or the AD.VI.S.OR hotline found at https://prolongedfieldcare.org/telemed-resources-for-us-mil/ or with infection prevention or infectious disease consultants (usarmy.jbsa.medcom-rhc-c.list.amedd-ic-consult@health.mil) or with infectious disease consultants through the AD.VI.S.OR hotline. Hepatitis C (HCV) prophylaxis is not recommended, but testing can be considered in penetrating blast injury at the time of injury and at two, four, and six months.[20]

- **Healthcare Bloodborne Pathogen Exposure**: Staff caring for patients with combat wounds are at risk for blood borne pathogens (HBV, HIV and HCV).[20] At risk activities include security personnel searching patients (for example, patting down patients who are injection drug users, needle sticks, break in surgical technique and blood splatters to non-intact skin, eyes or mucosa).
- **Source testing should be obtained for HBV, HIV and HCV**: Testing for HBV and HIV should be obtained at time of exposure and up to six months post-exposure.[21] There is no post-exposure treatment for HCV, although excellent and well-tolerated regimens to cure HCV do exist for patients who become infected.
    - **For HBV**, treatment is based on the source's HBV surface antigen (HBsAg) status and the exposed patient's vaccine completion and post-vaccine titer (anti-HBs >10 mlU/ml. Refer to the *2018 CDC Prevention of Hepatitis B virus infection in the United States: Recommendations of the Advisory Committee on Immunization Practices: A summary of the MMWR report*.[22]
    - **For high risk HIV exposure**, 28 days of post-exposure prophylaxis with antiretroviral therapy should be administered within 1-2 hours but no later than 72 hours post-exposure. Refer to Updated *U.S. Public Health Service guidelines for the management of occupational exposures to HIV and recommendations for post-exposure prophylaxis*.[21]

CARE OF COMBAT-INJURED PERSONNEL BASED ON ROLE OF CARE

See Appendix A: Recommendations to Prevent Infections Associated with Combat-related Injuries based on role of care.

- Infection prevention and control or antimicrobial utilization questions can be fielded through usarmy.jbsa.medcom-rhc-c.list.amedd-ic-consult@health.mil.
- Ideally, Role 2 and 3 facilities should have a designated Infection Prevention and Control Officer (IPCO) as an additional duty or a full-time position if supported by manning levels. The U.S. Army holds an Infection Control in the Deployed Setting course open to all branches. Army Training Requirements and Resource System catalogs the course as 6A-F22 and U.S. Central Command requires and funds the course for Role 3 IPCOs.

- All facilities responsible for trauma care should monitor adherence to antimicrobial prophylaxis regimens as listed in the JTS guidelines for infection prevention after combat-related injuries and present rates to providers regularly. Rates should include adherence to recommended agents and duration of therapy.
- Ideally, Role 3 facilities should have a designated antimicrobial stewardship officer as an additional duty if supported by manning levels. Proposed antimicrobial stewardship measures should be discussed with an antimicrobial stewardship expert prior to implementation.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

The population of interest are all trauma patients with penetrating injury or diagnosis of open wound (includes open fracture or joint).

INTENT (EXPECTED OUTCOMES)

1. All patients in the population of interest receive the preferred or alternate antibiotic, or reason for different choice is documented.
2. All patients in population of interest have antibiotic administered within 3 hours of injury.
3. All patients in population of interest have a duration of prophylactic antibiotic use less than 72 hours, or documentation of reason for extended use.
4. All patients in population of interest admitted to the ICU have daily antiseptic body cleaning (for example, Sage, Chlorhexadine).

PERFORMANCE/ADHERENCE MEASURES

1. Number and percentage of patients in the population of interest who receive the preferred or alternate antibiotic.
2. Number and percentage of patients in the population of interest who receive other antibiotics (or and reason for different choice of antibiotics is documented).
3. Number and percentage of patients in the population of interest who have an antibiotic administered within three hours of injury.
4. Number and percentage of patients in the population of interest who have a duration of prophylactic antibiotic use less than 72 hours or documentation of reason for extended use.
5. Number and percentage of patients in the population of interest admitted to the ICU that have antiseptic body cleaning daily.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The pervious sections constitute the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The JTS Chief, JTS Program Manager, and the JTS PI Branch will perform the system review and data analysis.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

APPENDIX A: RECOMMENDATIONS TO PREVENT INFECTIONS LINKED TO COMBAT-RELATED INJURIES

Recommendations to prevent infections associated with combat-related injuries based on role of care. *Criteria for allowing retained fragments to remain behind: entry/exit wounds < 2 cm; no bone, joint, vascular, body cavity involvement; no high risk etiology (for example, mine); no obvious infection; assessable by x-ray.*

Table 1. Recommendations to Prevent Infections Linked to Combat-Related Injuries

Common Surgical Diagnoses	Care Category	Recommendations
Role 1 (Prehospital)	Initial care in the field	• Bandage wounds with sterile dressings (avoid pressure over eye wounds) • Stabilize fractures • Transfer to surgical support as soon as feasible
	Post-injury antimicrobials	• Provide single dose point of injury antimicrobials (Appendix B) if evacuation is delayed or expected to be delayed
Role 1 and Role 2 without surgical support (lla)	Post-injury antimicrobials	• Provide intravenous antimicrobials for open wounds (Appendix B) within 3 hours of injury. • Provide tetanus toxoid and immune globulin as appropriate (see Appendix C). • Gram negative coverage with aminoglycoside or fluoroquinolone not recommended. • Addition of penicillin to prevent clostridial gangrene or streptococcal infection is not recommended. • Re-dose antimicrobials if large volume blood product resuscitation. • Use only topical antimicrobials for burns.
	Debridement and irrigation	• Irrigate minor wounds to remove gross contamination with normal saline, sterile, or potable water without additives. • Debridement and irrigation of large wounds should be done at a surgical facility (Role 2b or 3). • Do not attempt to remove retained deep soft tissue fragments meeting criteria listed above. • Provide cefazolin 2 gm IV x 1 dose. • Refer to the *JTS War Wounds: Debridement and Irrigation CPG*.
Role 2 with surgical support and Role 3	Post Injury Antimicrobials	• Provide intravenous antimicrobials (Appendix B), within 3 hours of injury. • Provide tetanus toxoid and immune globulin as appropriate (Appendix C). • Re-dose Cefazolin with each debridement until bone has soft tissue coverage (Appendix B). • Gram negative coverage with aminoglycoside or fluoroquinolone not recommended. • Addition of penicillin to prevent clostridial gangrene or streptococcal infection is not recommended. • Re-dose antimicrobials if large volume blood product resuscitation. • Use only topical antimicrobials for burns. • Refer to the *JTS Invasive Fungal Infection CPG* for dismounted blast injuries, high amputations, and cases of recurring necrosis on staged debridements.

Common Surgical Diagnoses	Care Category	Recommendations
		• Provide post splenectomy immunizations if indicated. (See the *JTS Blunt Abdominal Trauma, Splenectomy, and Post-splenectomy Vaccination CPG*.)
	Debridement and irrigation	• Refer to the *JTS War Wounds: Debridement and Irrigation CPG*. • Antimicrobial beads pouches, or topical powder may be used. • Do not attempt to remove retained deep soft tissue fragments if criteria above are met. • Do not obtain cultures unless infection is suspected. • Do not attempt primary wound closure (except for dura and face).
	Other Surgical Irrigation	• N/A
Role 4	Post-injury antimicrobials	• Re-dose Cefazolin for 24 hours with each subsequent washout involving exposed bone. • Antimicrobial beads or pouches may be used. • Refer to the *JTS Invasive Fungal Infection CPG* for dismounted blast injuries, high amputations, and cases of recurring necrosis on staged debridements. • Provide post splenectomy immunizations if not documented. (See the *JTS Blunt Abdominal Trauma, Splenectomy, and Post-splenectomy Vaccination CPG*.)
	Debridement and irrigation	• Refer to the *JTS War Wounds: Debridement and Irrigation CPG*. • Do not attempt to remove retained deep soft tissue fragments if criteria above are met. • Do not obtain cultures unless infection is suspected. • Wounds should not be closed until 3-5 d post-injury when wound is clean and all devitalized tissue is removed.
	Other surgical management	• N/A

APPENDIX B : POST-INJURY ANTIMICROBIAL AGENT SELECTION & DURATION

Post-injury antimicrobial agent selection and duration based upon injury pattern.

Table 1. Post-Injury Antimicrobial Agent Selection and Duration

Injury	Preferred Agent(s)	Alternate Agent(s)	Duration
Extremity Wounds (Includes Skin, Soft Tissue, and Bone)			
Skin, soft tissue, no open fractures	Cefazolin, 2 gm IV q6-8h†‡	Clindamycin (450 mg PO TID or 900 mg IV q8h)	24 hours
Skin, soft tissue, with open fractures, exposed bone, or open joints	Cefazolin, 2 gm IV q6-8h†‡ §	Clindamycin 900 mg IV q8h	24 hours initially and repeat with each subsequent I&D until soft tissue coverage.
Thoracic Wounds			
Penetrating chest injury without esophageal disruption	Cefazolin, 2 gm IV q6-8h†‡	Clindamycin (450 mg PO TID or 900 mg IV q8h)	1 day
Penetrating chest injury with esophageal disruption	Cefazolin, 2 gm IV q6-8h†‡ PLUS metronidazole 500 mg IV q8-12h	Ertapenem 1 gm IV x 1 dose, OR Moxifloxacin 400 mg IV x 1 dose	Stop 24 hours after definitive closure
Abdominal Wounds			
Penetrating abdominal injury with suspected/known hollow viscus injury and soilage; may apply to rectal/perineal injuries as well	Cefazolin, 2 gm IV q6-8h†‡ PLUS metronidazole 500 mg IV q8-12h	Ertapenem 1 gm IV x 1 dose, OR Moxifloxacin 400 mg IV x 1 dose	Stop 24 hours after control of contamination
Maxillofacial And Neck Wounds			
Open maxillofacial fractures, or maxillofacial fractures with foreign body or fixation device	Cefazolin, 2 gm IV q6-8h†‡	Clindamycin 900 mg IV q8h	24 hours
Central Nervous System Wounds			
Penetrating brain injury	Cefazolin 2 gm IV q6-8h. †‡Consider adding metronidazole 500 mg IV q8-12h if gross contamination with organic debris	Cetriaxone 2 mg IV q24h. Consider adding metronidazole 500 mg IV q8-12h if gross contamination with organic debris. For patients with a history of anaphylaxis or allergies to cephalosporins, vacomycin 15-20mg/kg IV q 8-12h PLUS ciprofloxacin 400 mg IV q8-12h	5 days or until CSF leak is closed, whichever is longer

Injury	Preferred Agent(s)	Alternate Agent(s)	Duration
Penetrating spinal cord injury	Cefazolin, 2 gm IV q6-8h.†‡ ADD metronidazole 500 mg IV q8-12h if abdominal cavity is involved	As above. ADD metronidazole 500 mg IV q8-12h if abdominal cavity is involved	
Eye Wounds			
Eye injury, burn or abrasion	Topical: Erythromycin or Bacitracin ophthalmic ointment QID and PRN for symptomatic relief. Systemic: No systemic treatment required	Fluoroquinolone 1 drop QID	Until epithelium healed (no fluoroescein staining)
Eye injury penetrating	Levofloxacin 750 mg IV/PO once daily + vancomycin 15-20 mg/kg IV q8-12h. Prior to primary repair, no topical agents should be used unless directed by ophthalmology	Moxifloxacin 400 mg IV/PO once daily	7 days or until evaluated by an ophthalmologist
Burns			
Superficial burns	Topical antimicrobials with daily dressing changes (include mafenide acetate** or silver sulfadiazine; may alternate between the two), OR silver impregnated dressing changed q3-5d, OR Biobrane	Silver nitrate solution applied to dressings	Until healed
Deep partial thickness burns	Topical antimicrobials with daily dressing changes, OR silver impregnated dressing changed q3-5d, PLUS excision and grafting	Silver nitrate solution applied to dressings PLUS excision and grafting	Until healed or grafted
Full thickness burns	Topical antimicrobials with daily dressing changes PLUS excision and grafting	Silver nitrate solution applied to dressings PLUS excision and grafting	Until healed or grafted
Point of Injury/Delayed Evacuation			
Expected delay to reach surgical care	Moxifloxacin 400 mg PO x 1 dose. Ertapenem 1 g IV or IM if penetrating abdominal injury, shock, or unable to tolerate PO medications	Levofloxacin 500 mg PO x 1 dose. Cefotetan 2 g IV or IM q12h if penetrating abdominal injury, shock, or unable to tolerate PO medications	Single dose therapy

**Post-injury antimicrobial agents are recommended to prevent early post-traumatic infectious complications, including sepsis, secondary to common bacterial flora. Selection is based on narrowest spectrum and duration required to prevent early infections prior to adequate surgical wound management. This narrow spectrum is selected to avoid selection of resistant bacteria. The antimicrobials listed are not intended for use in established infections, where multidrug-resistant (MDR) or other nosocomial pathogens may be causing infection.*

†Cefazolin may be dosed based on body mass: 1 gram if weight < 80 kg (176 lbs), 2 grams if weight 81-160 kg (177-352 lbs), 3 grams if weight > 160 kg (>352 lbs); doses up to 12 grams daily are supported by FDA-approved package insert.

‡Pediatric dosing: cefazolin, 20-30 mg/kg IV q6-8h (maximum, 100 mg/kg/day); metronidazole, 7.5 mg/kg IV q6h; clindamycin 25-40mg/kg/day IV divided q6- 8h; ertapenem, 15 mg/kg IV or IM q12 (children up to 12 years) or 20 mg/kg IV or IM once daily (children over 12 years; maximum, 1 gm/day); ceftriaxone, 100 mg/kg/day IV divided q12-24h (dosing for CNS injury); levofloxacin, 8 mg/kg IV or PO q12h (levofloxacin is only FDA-approved in children for prophylaxis of inhalational anthrax in children > 6 months of age, but this dose is commonly used for other indications); vancomycin 60 mg/kg/day IV divided q6h (dosing for CNS injury); ciprofloxacin, 10mg/kg IV (or 10-20mg/kg PO) q12h.

§These guidelines do not advocate adding enhanced Gram negative bacteria coverage (i.e., addition of fluoroquinolone or aminoglycoside antimicrobials) in type III fractures.

***Mafenide acetate is contraindicated in infants less than 2 months of age.*

††Post-injury antimicrobial therapy as suggested by the Acute Traumatic Wound Management in the Prolonged Field Care Setting CPG.

APPENDIX C: TETANUS PROPHYLAXIS RECOMMENDATIONS

Tetanus Prophylaxis recommendations from the Advisory Committee on Immunization Practices

Figure. Tetanus Immunization Chart

Tetanus Immunization Status	Minor Clean Wound	Major Clean Wound	Contaminated Wound (War Wounds)
Fully immunized recent Td booster	N/A	N/A	N/A
Fully immunized Td booster 5–10 years ago	N/A	Tdap	Tdap
Fully immunized, no booster for >10 years	Tdap	Tdap	Tdap
Unknown, none, or incomplete immunization	Tdap	Tdap and TIG (250U)	Tdap and TIG (500U)

N/A, not applicable; Td, tetanus and diphtheria; Tdap, tetanus-diphtheria-acellular pertussis; TIG, tetanus immune globulin.
***Note**: Tetanus vaccination of mother gives her protection and protects the newborn in the first few weeks of life.*

Source: Special Operations Forces Medical Handbook, U.S. DoD. Reprinted from the JTS Acute Traumatic Wound Management – Prolonged Field Care CPG, 24 Jul 2017

* Such as, but not limited to, wounds contaminated with dirt, feces, soil, and saliva; puncture wounds; avulsions; and wounds resulting from missiles, crushing, burns, and frostbite.

† DTaP is recommended for children aged <7 years. Tdap is preferred to Td for persons aged ≥11 years who have not previously received Tdap. Persons aged ≥7 years who are not fully immunized against pertussis, tetanus or diphtheria should receive one dose of Tdap for wound management and as part of the catch-up series.

§ Persons with HIV infection or severe immunodeficiency who have contaminated wounds should also receive TIG, regardless of their history of tetanus immunization.

.

APPENDIX D: POST EXPOSURE MANAGEMENT OF PERSONNEL

Post exposure management of personnel after occupational percutaneous and mucosal exposure to blood or any body fluids.

Table. Post Exposure Management of Personnel

Post Exposure Management of Personnel					
Healthcare Personnel Status	Post exposure testing		Post exposure prophylaxis		Post vaccination serologic testing †
	Source patient (HBs Ag)	HCP testing (anti-HBs)	HBIG*	Vaccination	
Documented responder § after complete series (≥3 doses)	**No action needed**				
Documented non-responder ¶ after 6 doses (2 complete series)	Positive/unknown		HBIG x2 separated by 1 month		No
	Negative	**No action needed**			
Response unknown after a complete series	Positive/unknown	‹ 10 mIU/mL	HBIG x1	Initiate revaccination	Yes
	Negative	‹ 10 mIU/mL	None		
	Any result	≥ 10 mIU/mL	**No action needed**		
Unvaccinated/incompletely vaccinated or vaccine refusers	Positive/unknown		HBIG x1	Complete vaccination	Yes
	Negative		None	Complete vaccination	Yes

(Morb Mortal Wkly Rep. 2018; 67(No. RR-1) [:1-31.])

Abbreviations: HCP – Healthcare Personnel; HBsAg – Hepatitis B surface antigen; anti-HBs – antibody to Hepatitis B surface antigen; HBIG – Hepatitis B immune globulin.

** HBIG should be administered intramuscularly as soon as possible after exposure when indicated. The effectiveness of HBIG when administered ›7 days after percutaneous, mucosal, or nonintact skin exposures is unknown. HBIG dosage is 0.06 mL/kg.*

† Should be performed 1-2 months after the last dose of the Hep B vaccine series (and 4-6 months after administration of HBIG to avoid detection of passively administered anti-HBs) using a quantitative method that allows detection of the protective concentration of anti-HBs (≥10 mIU/mL)

§ A responder is defined as a person with anti-HBs ≥10 mIU/mL after ≥3 doses of HepB vaccine.

¶ A nonresponder is defined as a person with anti-HBs ‹10 mIU/mL after ≥6 doses of HepB vaccine.

APPENDIX E : CHLORHEXIDINE ANTISEPTIC BODY CLEANING

(Adopted from LRMC Policy)

Policy: The chlorhexidine antiseptic body cleaning wash cloths will be used on all intensive care unit patients unless a patient declines or has any known sensitivities to ingredients.

Purpose: To reduce the risk of hospital associated infection by decreasing bacterial colonization that can cause skin infection.

Applicability: The antiseptic body cleaning wash cloths policy is applicable to all healthcare workers assigned to provide bedside bathing to patients in the medical facility.

Responsibility: It is the responsibility of the nursing managers to ensure that this policy is implemented correctly and consistently.

Exclusion: Avoid facial area, open wounds, and areas of 2nd or 3rd degree burned skin.

PROCEDURE

1. **When the patient arrives to the unit first bathe patient with soap/water add 30 cc of Hibiclens 4 % to the basin and bathe patient to remove all visible dirt.**
    a. Wait 6 hours after initial bath and bathe patient with antiseptic body cleaning washcloths once a day.
    b. Warming the antiseptic body cleaning washcloths (if warmer not available).
    c. Warm package in the dedicated microwave settings: 1000 watts for 30 seconds.
    d. Consult package for complete indications, ingredients, and warnings.
2. **Bathing a patient with antiseptic body cleaning washcloths**
    a. Wash hands prior to the procedure and don a pair of gloves and a gown.
    b. Explain the procedure to the patient.
    c. Ensure the patient has privacy. Have patient remove gown or assist in the removal as needed. Use a towel or sheet to cover the patient appropriately.
    d. Peel back the label on the package and test the temperature by touching the top washcloth. Remember, gloves diminish sensitivity to heat. If temperature is acceptable, proceed to the next step.
    e. Remove #1 washcloth.
        i. Test washcloth to back of patient's hand or inside wrist/forearm area.
        ii. Ask patient if the temperature is acceptable.
            - If acceptable, proceed with next step.
            - If NOT acceptable, STOP the procedure until temperature is acceptable to the patient.
            - Continue to monitor patient's comfort level with the temperature as the bath progresses.

f. For incontinence care, clean using terrycloth towels, soap and water, followed by wiping the involved skin with as many chlorhexidine cloths as necessary.

g. Apply clean gown, reposition and cover the patient.

h. Discard all disposables as general waste.

NOTE: Do not flush antiseptic body cleaning washcloths in the toilet!

i. Document procedure in progress notes.

Table. Wash cloth sequence

Cloth	Areas*	Action
***Do Not Use on Face**		
1	Both arms and chest	Discard
2	Perineum	Discard
3	Right Leg	Discard
4	Left Leg	Discard
5	Back	Discard
6	Buttocks	Discard

5. What To Do

a. Do use chlorhexidine (CHG) baths in place of daily bathing with soap and water.

b. Do massage firmly into skin to bind skin proteins and prevent bacteria for 24 hours.

c. Only use CHG-compatible lotions.

d. Use over superficial wounds, including stages 1 and 2 decubitus ulcers.

6. What NOT To Do

a. Do NOT use above jaw line.

b. Do NOT rinse or wipe off CHG. Let air dry.

c. Do NOT flush CHG cloths (discard in trash, not toilet or commode)

d. Do NOT include patients who are allergic to CHG.

APPENDIX F: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Inhalation Injury and Toxic Industrial Chemical Exposure

There are multiple toxic industrial chemicals that act on the respiratory tract. This CPG reviews common toxic industrial chemicals related in pulmonary injury

PURPOSE

There are multiple toxic industrial chemicals that act on the respiratory tract. This CPG reviews the most common toxic industrial chemicals which lead to pulmonary injury.

More information is available from the Centers for Disease Control and Prevention:

- https://www.atsdr.cdc.gov/toxicsubstances.html
- Textbooks of Military Medicine https://medcoe.army.mil/borden-3-textbooks-of-military-medicine
- Patients with both burn and inhalation injury have significantly increased morbidity and mortality compared to those with burn injury alone.[1] This CPG is intended to review relevant information in the care of patients with inhalation injury and more specifically toxic industrial chemicals. Also included is a brief overview of the management strategies for these patients. We intend to inform caregivers with the goal of reducing some of the complications of inhalation injury.

GENERAL SMOKE INHALATION INJURY

Smoke inhalation injury occurs from several agents. Thermal injury and chemical injury are the primary initial toxicities. Chemical injury occurs from several materials of combustion and pyrolysis.[2] Highly water-soluble irritants such as acrolein, sulfur dioxide, hydrogen chloride and ammonia, and intermediate water soluble irritants such as chlorine and isocyanates are produced. Poorly water-soluble irritants are oxides of nitrogen and phosgene. Simple asphyxiants which displace oxygen include carbon dioxide and methane, and chemical asphyxiants which inhibit mitochondrial activity and reduce hemoglobin carrying capacity include carbon monoxide, cyanide, and hydrogen sulfide. Treatment is generally supportive. Some require antidotes. Most critically ill patients require unique ventilation techniques used for Acute Respiratory Distress Syndrome (ARDS). As toxic pulmonary agents lead to oxidative damage to lung tissues, similar to excessive oxygen supplementation, oxygen supplementation should be provided only as necessary to maintain sufficient oxygenation (pulse oximetry of 90% to 96%).[3]

TOXIC INDUSTRIAL CHEMICAL INHALATIONAL INJURY

In general, the treatment of ARDS secondary to toxic industrial chemicals is similar to that for smoke inhalation injury. The care is supportive with a focus on:

- Airway management.
- Lung-protective ventilation strategies.
- Aggressive pulmonary toilet.
- Avoidance of volume overload or rapid fluid infusion that might worsen pulmonary edema secondary to capillary leak.

PATIENTS REQUIRING MECHANICAL VENTILATION (MV) SECONDARY TO TOXIC INDUSTRIAL CHEMICAL INHALATION

Patients requiring MV secondary to toxic industrial chemicals inhalation, in particular chlorine, are at a higher risk of developing ventilator-associated pneumonia and should be monitored closely. The treatments in this CPG are primarily based on animal experiments. Evidence for clinical use in humans is limited.

CHLORINE

Chlorine (Cl_2) (Appendix A) is used commonly in industry. It is a commonly found in industrial and transportation accidents and are sometimes used in weapons such as improvised explosive devices. Chlorine dissolves in water to form hydrochloric and hypochlorous acids.

Chlorine has intermediate water solubility. Just after exposure the patient develops mucosal irritation (tearing, skin burning, drooling), but after large or sustained exposure the patient may develop cough, shortness of breath, and chest pain due to alveolar injury. Except for in cases of large exposure, upper airway symptoms proceed lower airway symptoms. If the patient develops pulmonary toxicity, it may worsen over days.

Treatment is primarily skin decontamination, supplemental oxygen as necessary, beta agonists and ARDS ventilatory techniques.[4] Inhaled corticosteroids (e.g., fluticasone) improved secondary outcomes in severely toxic animal models.[5] Clinical data on the efficacy of corticosteroids after human exposure to lung-damaging agents are inconclusive as the number of well-structured controlled studies is small and the indications for administration of corticosteroids are unclear.[6] Prone positioning mechanical ventilation may be effective.[7] Nebulized bicarbonate has not reliably improved outcomes.[4,6,8,9]

PHOSGENE

Phosgene (Carbonyl chloride, $COCl_2$) has a sweet, pleasant smell of mown hay. It is poorly water soluble, not noxious and does not prompt escape from the location by the victim. It was used in WWI as a chemical weapon. It is produced from the combustion of chlorinated hydrocarbons (welding, fires) and from synthesis of solvents (degreasers, cleaners). Phosgene is a respiratory irritant. Immediate effects may include coughing, burning sensation in throat and eyes, lacrimation, blurred vision, dyspnea, nausea and vomiting, and or cutaneous injury. High-dose inhalation may cause onset of pulmonary edema within 2-6 hours. High concentrations may produce a severe cough with laryngospasm that results in sudden death; this possibly could be due to phosgene hydrolysis, which releases free hydrochloric acid at the level of the larynx. On the other hand, delayed-onset pulmonary edema as late as 48 hours after exposure is also possible. Thus, patients should be monitored for that length of time after exposure.[10] The mechanism of toxicity is release of hydrochloric acid and reactive oxygen species and free radicals in the lung epithelial layers. Decontamination is typically not needed once the patient leaves the exposure. Treat with observation, supplemental oxygen, and ARDS ventilation techniques.

HYDROGEN SULFIDE

Hydrogen sulfide (H_2S) smells like rotten eggs and is a chemical irritant. Exposures occur in waste management, petroleum, natural gas industries, and asphalt and rubber factories. The gas acts like cyanide and inhibits cytochrome oxidase, preventing mitochondrial oxygen use and cellular respiration. At lower doses, H_2S causes skin and mucous membrane irritation. At high concentrations, it produces a “knockdown” effect, a sudden loss of consciousness. At these concentrations it can produce seizure, myocardial ischemia, keratoconjunctivitis, and upper airway and pulmonary injury. The vast majority of patients will have died prior to receiving medical care or will make a full recovery immediately after removal from the exposure. In those patients who do not immediately recover after removal from the exposure, treat with supplemental oxygen and intravenous hydroxocobalamin (5 g) or intravenous sodium nitrite (300 mg), and supportive care.[2] Inhalation of sodium nitrite is associated with methemoglobinemia and hypotension. Infuse it over 5-7 minutes.

AMMONIA

Ammonia (NH_3) is a common industrial and household chemical used as a fertilizer, refrigerant, cleaning agent. NH_3 has a pungent odor. It is also used in plastic and explosive synthesis. NH_3 is transported under pressure in liquid form at sub-zero temperatures. It reacts with water upon release, to form ammonium hydroxide (NH_4OH), a strong base, which produces mucosal irritation (tearing, skin irritation, eye pain and burns), severe upper airway irritation, and alkali skin burns. High concentrations or prolonged exposure duration (patient unconscious in a closed room) can produce tracheobronchial and pulmonary inflammation. It can produce respiratory failure within 2-5 minutes of exposure. Treat with skin and eye irrigation, alkali burn skin care, supplemental oxygen as necessary, ARDS ventilatory techniques, and supportive care.[4] Proper eye care, particularly copious irrigation, is essential immediately after the exposure. The eye is often the forgotten organ in a patient with an acute irritant gas exposure.[11]

OTHER COMMON CHEMICAL TOXINS RELATED TO INHALATIONAL EXPOSURES

CYANIDE

Cyanide (CN) is released in structural and vehicle fires and in occupational settings of chemical or synthetic material combustion. It is used in manufacturing of pesticides and synthetic materials, metal extraction, and in chemical laboratories. Cyanide inhibits mitochondrial cytochrome oxidase thereby halting cellular respiration and aerobic metabolism. Early or mild effects are mostly neurologic (dizziness, headache, nausea, and anxiety). Late or severe effects are coma, seizure, respiratory depression, hypotension, and tachycardia. ARDS and pulmonary edema can occur in severe cases. Coma precedes apnea, and then hypotension develops.

The triad of severe toxicity is hypotension, altered mental status, and lactic acidosis (commonly > 8 mmol/L).[12] Treat with oxygen, mechanical ventilation, and rapid administration of an antidote. Hydroxocobalamin, the most commonly available antidote (sold as Cyanokit®), binds to CN to form cyanocobalamin, which is nontoxic and excreted in the urine. The standard dose of 5 g is infused intravenously over 15 minutes. A second dose of 5 g can be administered in patients with severe toxicity or poor clinical response. It is generally regarded as safe. Red discoloration of the skin and urine is common which may interfere with colorimetric assays. Hydroxocobalamin has been compared to sodium nitrite (300 mg) and sodium thiosulfate (12.5 g), prior treatment options, and was found to be superior with less toxicity and the latter two therapies are now not recommended for severe cyanide toxicity.[13] Treatment with nitrites carries significant risk of hypotension and methemoglobinemia, which can further jeopardize tissue oxygen delivery.

CARBON MONOXIDE

Carbon monoxide (CO) is released from the combustion of carbon containing compounds with combustion engines and cooking stoves in enclosed spaces. CO has a high affinity for hemoglobin and displaces oxygen when present. This displacement of oxygen ultimately leads to decreased oxygen delivery at the tissue and mitochondrial level.[14] Symptoms of CO toxicity include confusion, stupor, coma, seizures, and myocardial infarction.[15] CO levels are traditionally measured using a co-oximeter, in a blood gas lab; however, this testing may not always be available and a high index of suspicion must be present as elevated CO may be present despite normal PaO2 and SpO2 readings. Newer non-invasive CO-oximetry may allow for early diagnosis and better monitoring.[16] Treatment of CO poisoning involves producing 100% oxygen, shortening the half-life of CO binding to hemoglobin to about 45 minutes. Hyperbaric oxygen therapy (HBO) has been used to reduce the half-life to about 20 minutes.[17] Logistical factors have limited the utilization of HBO and a systematic review found that not enough evidence exists at this point to determine definitively whether HBO reduces adverse neurologic outcomes after CO poisoning.

FIRE SUPPRESSANTS

Chemical fire suppressants are released in military vehicle fires. The most common is HFC227 (HFC-227EA, heptafluoropropane). It replaced bromotrifluoromethane (one of many "Halons") in military vehicles.[18] These "virgin Halons" were banned by the Environmental Protection Agency (EPA) in 1994.[19] HFC227 is inert, a simple asphyxiant, and no cases of combustion related toxicity have been published or reported to the EPA or Occupational Safety and Health Administration.[20,21] HFC227 can convert to hydrogen fluoride in small amounts during a fire, and; treatment is supportive, similar to other chemical exposures resulting in inhalation injury.[4] Hydrogen fluoride (HF) as a byproduct of combustion with standard fire suppression systems may cause severe inhalation injury. Exposure to HF may result in rapidly progressive or fatal respiratory failure despite minimal external evidence of injury. In human tissue, HF dissociates into the hydrogen and fluoride ions. Fluoride ions rapidly bind calcium, leading to fatal hypocalcemia induced cardiac dysrhythmias. Patients present typically with shortness of breath, cough, or hypoxia; there must be a high level of suspicion. The administration of nebulized calcium gluconate (1.5 ml of 10% Ca Gluconate in 4.5 ml water) every 4 hours may provide benefit. If the patient is hypocalcemic, intravenous calcium gluconate (1000 mg) or intravenous calcium chloride (1000 mg) through a central venous line) should be administered and repeated every 15 minutes until normalization of serum calcium for a minimum of 12 hours. In the absence of significant burns, consider steroids if symptoms do not improve. Bronchopneumonia can develop within the first week.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All patients diagnosed with smoke or toxic chemical inhalation exposure.

INTENT (EXPECTED OUTCOMES)

1. Patients with respiratory insufficiency and chemical exposure are intubated by the first surgical team admitting.
2. Examination of pharynx, larynx, trachea, and bronchi is documented for all patients in population of interest.

PERFORMANCE/ADHERENCE METRICS

1. Number and percentage of patients with respiratory insufficiency who receive intubation.
2. Number and percentage of patients in population of interest who have documentation of examination of pharynx, larynx, trachea, and bronchi.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the Joint Trauma System (JTS) Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

APPENDIX A: CHLORINE INHALATION

Stratify chlorine toxic patients into no symptoms, mild, moderate, and severe. Treatment and observation periods can be tailored based on the severity of symptoms.

1. **No symptoms.** If no symptoms, then may be discharged if initial assessment (respiratory examination, vital signs, and pulse oximetry) is normal.
2. **Mild** (minimal symptoms, coughing, normal pulse oximetry, and no increased respiratory effort). Obtain chest radiograph, administer inhaled beta agonists, and observe for up to 6 hours. Most patients can be discharged.
3. **Moderate** (hypoxia, increased respiratory effort, normal chest radiograph) - Obtain chest radiograph, administer beta agonists, and admit for at least 12 hours. Consider inhaled steroids (fluticasone 200 mcg or similar agent) twice a day, early endotracheal intubation for increased respiratory effort, and inhaled ipratropium.
4. **Severe** (hypoxia, respiratory distress, often require intubation). Perform early endotracheal intubation with 8.0 tube to allow for bronchoscopy, obtain chest radiograph, administer beta agonists, and admit to ICU. Administer humidified oxygen and inhaled steroids (fluticasone 200 mcg or similar agent) twice a day. Consider inhaled ipratropium if not improving. If unable to administer inhaled steroids or if patient has significant bronchoconstriction consider intravenous steroids.

   ARDS. Perform similar ventilation strategies for ARDS, including increased positive end-expiratory pressure and low tidal volumes. Evaluate daily for barotrauma. The patient may require high doses of sedatives to maintain synchrony with the ventilator.

IMPORTANT CAVEATS

A patient who is close to a large, dense chlorine exposure (IED detonated chlorine tank) or suffers a sustained exposure (unconscious in a chlorine filled room) may develop upper airway edema. In these cases, perform early intubation. Examine all exposed patients for eye, mucosal, and skin contamination which is manifested by corneal burns/abrasions, mucosal swelling, and skin erythema, blister, or burns. Decontaminate all symptomatic skin surfaces. Remove all exposed clothing. The trauma evaluation and treatment takes priority over the chlorine toxicity. Nebulized bicarbonate has not been reliably effective. It is made by mixing 1 ml of 8.5% sodium bicarbonate in 3 ml saline to create a 2% solution.

POST DISCHARGE FOLLOW-UP

If available, obtain pulmonary function tests with lung volume assessment and diffusing capacity of the lungs for carbon monoxide. If the pulmonary function test is abnormal, obtain high resolution pulmonary CT scan to assess or pulmonary fibrosis.

BACKGROUND AND CLINICAL EFFECTS

Chlorine is a gas with intermediate water solubility. It will induce mild irritant symptoms (tearing, pungent smell, upper airway irritation), but will also induce delayed pulmonary edema following a dense or sustained exposure. Chlorine dissolution into lung water generates hydrochloric acid and hypochlorous acid. The hypochlorous acid decomposes to HCl and nascent oxygen (O-). The nascent O- produces additional lung damage by free-radical formation. Chlorine was used in World War I as a chemical warfare agent.

- **Early effects.** Irritation of the eyes, nasal mucosa, upper airway, coughing, shortness of breath, and chest pain or burning
- **Late effects.** Pulmonary congestion and edema and then ARDS.

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Interfacility Transport of Patients Between Theater Medical Treatment Facilities

This CPG recommends the minimum requirements to move critical care casualties after their entry into the evacuation system.

INTRODUCTION

Reducing the time to required medical or surgical interventions prevents death in potentially survivable illness, injuries and wounds. When evacuation times are extended, en route care (ERC) capability must be adequately expanded to mitigate the delay. In January 2010, the *Joint Force Health Protection Joint Patient Movement Report* stated "the current success of the medical community is colored by the valiant ability to overcome deficiencies through "just-in-time workarounds;" many systemic shortfalls are resolved and become transparent to patient outcomes. However, future operations may not tolerate current deficiencies."[1] This Joint Trauma System (JTS) Clinical Practice Guideline (CPG) recommends the minimum requirements and capabilities for the movement of critical care patients between medical treatment facilities (MTFs). It is designed to mitigate historically recognized and potential future systemic shortfalls with the ultimate goal of improving case fatality rates, reducing morbidity, and eliminating preventable death. This guideline is also referred to as the inter-facility transport CPG for policy adoption within a Geographical Combatant Command (GCC) or Area of Operations (AOR). The focus of this guideline is to establish a system of systems approach to identify the clinical and operational elements essential to optimizing the ERC of patients during inter-facility transport across a combatant theater, to include austere and far forward locations. Transport may occur via land, sea, or air and involve multiple agencies or coalition partners.

Successful implementation of this CPG first requires medical personnel with the appropriate education, training and capabilities throughout the ERC system. Secondly, the use of specialized transport equipment, supplies, and protocols required to meet the clinical needs of patients in transit are detailed. Also, it cannot be over emphasized that success requires effective coordination between the medical team, vehicle operators and the command providing the vehicles. Care capability is almost always reduced during ERC. The tyranny of distance is related to time. Further complicating this threat with en route delays will contribute to preventable deaths. Effective communication, coordination and cooperation across the system mitigate this risk.

Through this CPG, the Committee on En Route Combat Casualty Care (CoERCCC) and the JTS strongly recommend the establishment of a positive, proactive and responsive medical direction capability along with dedicated medical dispatch centers to facilitate patient care and safety during the phases of transport. These phases consist of pre-movement (e.g., patient preparation and packaging), en route (e.g., continuation of care and management of acute complications), and post-movement (e.g., review of documentation and patient outcomes) overseen by direct and indirect medical leadership. A systems of systems approach will help mitigate the risks associated with patient transport, and as described in this CPG will include: expected ERC capabilities, types of ERC providers, transport platforms and medical materiel, dispatch centers, medical direction, treatment protocols, documentation of care requirements, and patient transfer criteria.[1]

Unity of command is critical in this endeavor. While "unity of effort" suggests that multiple parties are working toward a shared goal in a coordinated way, it is not the same as "unity of command." Unity of command represents a unified and focused effort that is essential for success in complex objectives. Specifically, "unity of command" is predicated on one person ultimately being in charge of the process though many people are working toward the outcome.[2] Commanders must establish leadership positions with defined roles, responsibilities and the delegated authority to execute successful ERC. Competent military authority of the ERC system is required because success involves the synchronization of multiple teams, the transfer of patient care across those teams, and the myriad challenges of delivering care in operational environments. Subsequently, capability requirements for ERC must be established, promulgated and effectively enforced to ensure that the capability to deliver life-saving ERC is afforded the ill, injured and wounded.

This guideline is specifically concerned with the inter-facility transport of patients between the intra-theater roles of care including transfer between MTFs and civilian treatment facilities. Please refer to Tactical Combat Casualty Care-Tactical Evacuation Care guidelines for Point of Injury (POI) transport and to Aeromedical Evacuation (AE) guidelines for inter-theater transport.

It is important to note, in an immature theater of operations or in a larger scale conflict, casualty numbers may exceed available resources. When this occurs, compliance with this guideline may be compromised. Commanders need to ensure appropriate patient movement resources are a priority, especially for critical care transports between treatment facilities.

BACKGROUND

After years of conflict in Iraq and Afghanistan, the Military Health System is rightly proud of a 98% casualty survival rate for patients reaching a Role 3 facility. Unfortunately, this statistic excludes those casualties who die before reaching the Role 3 facility. According to Eastridge et al in *Death on the battlefield (2001–2011): Implications for the future of combat casualty care,* 87.3% of the total combat deaths occur prior to arrival at the Role 3 facility, highlighting the opportunity for further improvements.[3] ERC is a significant patient care component both from the POI to an MTF and after damage control resuscitation and surgery to the next MTF or to an aerial port of debarkation (APO) for movement out of theater.

Inter-facility transport presents an "added challenge" and is associated with increased risk to the patient.[4,5] These movements typically occur in combatant vehicles and, due to physical space limitations and operational demands, there are fewer providers giving care. And, while the number and complexity of interventions are limited, they are also more difficult to execute. Noise, vibration, and cramped spaces act together to disconnect lines, displace tubes, shift dressings, impede patient monitoring, and directly antagonize injuries. Environmental conditions and inclement weather during transport can contribute to morbidity and mortality. If flying, the reduced barometric pressure results in lowered partial pressure of oxygen, increased size of gas pockets, decreased tissue perfusion, and increased tissue swelling.[6] The enemy and diplomatic considerations may also effect routes, duration of transport and the safety of movement. Good ERC systems and teams recognize these risks and mitigate their threats.

Transporting patients is a medical intervention itself and although very common still has risks and benefits. A central tenet of combat medicine is clearing the battlefield by transporting patients between facilities. Transport may be required because of the patient's condition or the organization's mission. The reality of war and military doctrine is that casualties must be evacuated until they receive definitive treatment. Consolidation and centralization of medical resources reduces their physical footprint, diminishes the need for re-location during combat maneuvers, avoids the loss of medical capability during re-location, and decreases the associated global logistical demands on the combatant command. The decision to transport is nearly reflexive, and rightly so. But, the risks inherent to transport must be minimized through a robust system of care dedicated to optimizing patient outcomes during transport. Besides the direct medical risk to the patient of the physical movement, loss of the transport asset and crew to accident or enemy action is real. There are many recurrent examples of both civilian and military medical evacuation helicopters being lost to environmental threats and enemy action flying missions that were probably not critical to life, limb or eyesight.

PATIENT STABILIZATION

In order to minimize transport contribution to morbidity and mortality, optimal but not necessarily definitive patient stabilization before transport is critical and encompasses four connected elements. First, injuries—actual and potential (e.g. spinal instability)—must be controlled. This usually happens at the earliest phase of tactical combat casualty care. Second, resuscitation must be optimized but may be ongoing. The best outcomes occur when a patient's physiology is closest to normal before transport.[7,8] Patient variables that best indicate adequate resuscitation for transport continues to be an area for continued basic and translational research.[9,10,11,12] Third, other treatments besides resuscitative measures should be at steady-state, not requiring dynamic, complex, or life-preserving adjustments en route. Until technology progresses, the planned initiation of new interventions or the continuation of complex or capability unique interventions during transport are

discouraged. Finally, deterioration requiring en route intervention must be anticipated and prevented with risk mitigation procedures prior to departure. Examples include placing lines or tubes, or decompressing compartment syndromes, as well as providing adequate analgesia for the increased pain of transport. This requires an understanding of the injury course as well as the transport environment.

Preparation for transport must include more than just patient physiology. Packaging to ensure safety during the transitions of care is also essential. This includes the logistical and the indirectly clinical aspects of getting the patient ready for transfer from the treatment facility to the ERC team. Many of these steps can be managed by the non-physician members of the transferring team but must be verified by the ERC providers prior to departure.

EXPECTED ERC CAPABILITIES

Medical capability is the quality or state of being able to provide the expected and required medical services and support to the casualty. Within the system of en route care, and when capability is discussed in this document, it is the ready and available potential to provide the required critical care in a proficient and timely manner. It includes the physical and mental talent of the team, as well as the physical presence of all medical materials and equipment in the vehicle that are expected by theater policy. A capability does not exist if the personnel are not proficient or if they are missing medical supplies and equipment. Nor is capability present if the ERC team is not integrated effectively with the transport platform team. Therefore, units must be conversant and compliant with the published theater standards along with being physically and materially ready to execute the assigned mission. Within the operational theater it is critical to ensure actual capability is effectively communicated between medical control, the transferring facility, the ERC team, and the receiving facility. The ERC organization has a moral, ethical and legal obligation to ensure they can carry out their mission essential task list and mission essential care capability for the patient. If not, they must notify their commander, the medical director, and the medical dispatch center that they are unable to provide the expected and required care to our critically ill, injured or wounded patients. Since medical evacuation is a theater asset, the local unit commander cannot legitimately accept risk for the theater commander. Locally accepting risk of a reduced capability compromises care, contributes to excess morbidity and mortality and is inconsistent with the effective and efficient use of medical dispatch centers. It is the center's mission to select and assign the appropriate evacuation asset to the right mission.

A minimum of two levels of capability are recognized in this guideline: Critical Care and Intermediate Care. The ideal military ERC system will be a scalable and modular asset with appropriate resource allocation to provide a full range of patient care services to include advanced clinical capabilities.

Critical Care transport is required when "the patient has a critical illness or injury that acutely impairs one or more vital organ systems such that there is a high probability of imminent or life-threatening deterioration in the patient's condition during transport." For success, en route critical care must be provided by a team of providers "with the requisite decision making skills of high complexity to assess, manipulate, and support vital organ system failure and/or to prevent further life threatening deterioration of the patient's condition during transport."[13] Ideally, this team will be led by a physician or other independent practitioner with extensive critical care experience and the requisite equipment to perform lifesaving interventions as required by the clinical scenario.

Sometimes a completely packaged and fully stabilized patient is operationally unrealistic. Some injuries or illnesses cannot be stabilized due to capability limitations. Limited capability may be the driving indication for transport. These transfers are fraught with the risks of undesired outcomes during transport. Subsequently, the transferring provider should document the indications for transport before patient movement, continue the resuscitation and ensure adequate (even higher) capability of the ERC. The gold standard for unstable patient

transport is movement with critical care capability led by a physician who is qualified, experienced, and proficient at critical care transport.

Intermediate ERC should be initiated for a patient that does not require critical care but is in need of a dedicated medical attendant with at least the knowledge and skills equivalent to a paramedic as defined by the National Emergency Medical Services (EMS) Scope of Practice Model. Adequate medical supplies to perform lifesaving interventions as well as ongoing resuscitation are also necessary. Patients in this category have some complexity of care delivery that must be maintained by a medically skilled provider but are not expected to deteriorate during the period of the patient movement.

Required ERC capability should be based on the current condition of the patient being transferred and their expected course during transport. This is determined by the transferring provider. If the requested level of ERC is not available, then a higher level of care should be provided. If this is not an option, then the transferring provider and the operational commander must carefully weigh the risks of patient transfer using a lower capability versus the risks of transport delay.

COMMANDERS

Joint Publication 1 states that, "…doctrine will be followed except when, in the judgment of the commander, exceptional circumstances dictate otherwise." The Commanders have specific responsibilities under Title 10, United States Code (USC), to organize, train, equip, prepare, and maintain their forces. For the purposes of this document that responsibility is ERC capability. Commanders are delegated the authority to accomplish their assigned missions but cannot absolve themselves of the responsibility for the attainment of these missions. Commanders of dedicated medical evacuation organizations shall not individually assume risk when they are not capable of providing the required intratheater ERC capability. Any risk assumption of reduced capability should be assumed by the theater commander as medical evacuation is a theater level responsibility. It is the commander's duty to notify higher command if they cannot execute their mission essential task list. Inherent to ERC within the mission essential task list is the capability to care for the patient with the level of care that is expected and required by the mission and the condition of the patient. Except as noted in Joint Publication 1 regarding exceptional circumstances, the advertised capability must be present during transport or increased morbidity and mortality rates will result. This has been demonstrated across evidence-based medical reviews and studies.[1]

TYPES OF ERC PROVIDERS

Health care teams are comprised of a variety of different provider types, and the ERC mission is no exception. ERC providers must receive formal education and training to ensure platform familiarization and vehicle crew resource management. Updating military ERC systems based on cautious application of civilian best practices should be tempered by a realistic understanding of operational considerations. Over 67% of civilian Helicopter Emergency Medical Services (HEMS) agencies in the United States staff their helicopters with Critical Care Flight Nurse/Critical Care Flight Paramedic teams.[14] Most ground EMS agencies use some variation of an Emergency Medical Technician (EMT) and Paramedic team. International HEMS agencies frequently use physician-led critical care transport teams.

The National EMS Scope of Practice Model is the core document that describes scope of practice for civilian EMS providers in the United States. These civilian levels of EMS provider, typically applied to enlisted medical providers, are Emergency Medical Responder, EMT, Advanced EMT, and Paramedic. Registered Nurses with education and training applicable to prehospital care have several advanced certifications available to validate their skill and knowledge proficiency, to include: Critical Care Flight Nurse, Certification in Emergency Nursing, Critical Care Registered Nurse, and others. Although not common in the United States, several international EMS systems educate, train, and certify physicians as prehospital providers and the United Kingdom (UK) Medical

Emergency Response Team (MERT) platform is the most well-known from use in the Regional Command South of Afghanistan.

Higher competency and capability improves case fatality rates when patients are transported. During Operation Enduring Freedom, care provided by critical care flight paramedics showed a 66% lower risk of 48-hour mortality compared with that of basic level EMTs.[15] In the UK, prehospital critical care is provided by physician-staffed HEMS. These teams have demonstrated survival in cases previously thought to be non-survivable (e.g., traumatic cardiac arrest).[16] British military platforms with on board intensivists have likewise demonstrated improved survival in more severely injured patients.[17]

It is imperative to understand the attributes of the different provider types based on their qualifications and certifications. Instrumental to ensuring capability is the verification of currency of their practice experience and their skill proficiency. Additionally, well trained teams improve outcomes so ERC teams who train together prior to operational assignment may optimize patient outcomes.

TRANSPORT PLATFORMS AND MEDICAL MATERIEL

Patient transport is conducted as a planned component of a given mission aboard dedicated vehicles or transports of opportunity. Understanding the capabilities and limitations of the transport platform will help ERC providers, mission planners, and medical control optimize the care they deliver. This requires the appropriate selection capability to conduct the mission based on the provider team, resuscitative equipment, treatment protocols and vehicular capabilities to move through the environment. For some ERC missions, the transport may require serial transfers between different vehicles and modes of transport. Familiarization with the different vehicles available in a theater of operations is imperative.

Weight and space restrictions, as well as the challenges of patient transport in an operational setting, necessitate the deliberate and careful selection of medical materials for a given mission. The provider's competency and the medical material actually present in the vehicle determine ERC capability. Vehicle selection will directly impact personnel and equipment availability and determine the highest level of care. Vehicles should be chosen with an understanding of the patient condition and must be appropriate for the type of ERC provider. Specific medical materials designated as patient movement items (PMI) must be available to support the patient during every phase of transport. Examples of PMI include ventilators, patient monitors, pulse oximeters, suction machines, IV pumps, oversized litters, negative pressure wound vacuums, pneumatic compression stockings/devices and more.[18] It is important the transferring facility request these items so that they can be loaded and transported with the ERC team. Whenever possible, the expendable medical supplies like oxygen from the transferring facility should be used until the last safe moment before departure. This action conserves the onboard medical supplies which cannot be replenished without stopping and delaying the transport. Additional information on PMI is found in the Aeromedical Evacuation Equipment Standards (AFI 10-2909), JP 4-02 and FM 4-02.1.

DISPATCH CENTERS

Tasking of limited resources while providing an appropriate ERC response requires a dedicated team with a comprehensive and current understanding of its assets and their current capabilities. This dispatch center should allocate resources based on mission requirements, the request of the transferring provider, the expected need from across the catchment area, and the capabilities of the available ERC units. Medical evacuation dispatch centers can vary but all should be co-located within a command and control (C2) communications center to coordinate efforts. Examples of dispatch centers include the U.S. Army's Theater Patient Movement Center for ground and rotary air ambulance medical evacuation and the joint activity Patient Movement Requirements Center for fixed wing aeromedical evacuation assets. Some multi-national AORs have Patient Evacuation Coordination Cells as dispatch centers for medical evacuation.[19,20,21] Whatever the configuration of

the dispatch center, they require detailed information to ensure the best allocation of available resources. This detailed information includes the validation and the verification of capability as resources increase and decrease with operational tempo and demands.

The 9-line medical evacuation request provides critical decision-making information in a standardized message format that helps expedite the medical evacuation process. A patient's condition, the operational situation, terrain, weather conditions, enemy threat and availability of assets are communicated in the 9-line request and taken into consideration by the dispatch center when determining the best transport vehicle and type of provider to send. Accurate medical evacuation precedence determination ensures an appropriate dispatch of capability. Urgency of medical care provided by the transferring facility is used to determine the medical evacuation precedence. The senior military person (or designated on-ground mission commander) present in coordination with the senior medical person determines when to request medical evacuation and the precedence assigned to the patient for evacuation. The on-site personnel should determine the evacuation precedence and discrepancies between the ground force precedence and the dispatch center will err on the side of higher acuity with further discussion reserved for after mission completion and the immediate run review process.

CAUTION: *Terminology used to communicate precedence is not consistent across services. Terminology for air (rotary wing) and ground ambulances shall be used for inter-facility transports and is provided in Table 2.*

Table 1. NATO 9 Line Medical Evacuation (MEDEVAC) Request

Line	Title	Explanation	Reason
1	Location/Pick up site	Eight or ten digit grid coordinates of pick up site	Required to know where to pick up the patient
2	Radio frequency, call sign	Frequency of radio at the pickup site Call sign of the person to be contacted at the pickup site	Evacuation vehicle can contact requesting unit while en route
3	Number of patients by precedence	A—URGENT B—URGENT-SURG C—PRIORITY D—ROUTINE E—CONVENIENCE	Assist command and control in prioritizing evacuation unit missions
4	Special equipment required	A—None B—Hoist C—Extraction equipment D—Ventilator	Required to have needed equipment loaded prior to mission start
5	Number of patients by type	L+# of patients–Litter A+# of patients– Ambulatory (sitting)	Needed to have appropriate number of vehicles dispatched
6	Security of pick-up site (wartime)	N—No enemy troops in area P—Possibly enemy troops in area (approach with caution) E—Enemy troops in area (approach with caution) X—Enemy troops in area (armed escort required)	For situational awareness and planning
6	Number and type of wound, injury or illness (peacetime)	Specific patient information on wound type (gunshot, blunt force, or explosive device) Serious bleeding and patient blood type if known	Assists evacuation personnel in determining required treatment and special equipment needed

Line	Title	Explanation	Reason
7	Method of marking pickup site	A—Panels B—Pyrotechnic signal C—Smoke signal D—None E—Other	Assists the evacuation crew in identifying the specific location of the pick up
8	Patient nationality and status	A—U.S. military B—U.S. civilian C—Non-U.S. military D—Non-U.S. civilian E—Enemy prisoner of war	Assists in planning for destination facilities and the need for guards.
9	Chemical, biological, radiological, and nuclear contamination (wartime)	Include this line only when applicable C—Chemical B—Biological R—Radiological N—Nuclear	Assists in planning for the mission.
9	Terrain description (peace time)	Identify terrain features in and around proposed landing or pickup site (lake, tower, ridge, mountain).	
+ 	M I S T	M – Mechanism of injury I – Type of Injury S – Signs (vital signs) T – Treatment given	Recently incorporated into use. May also include adult or child notification.

Table 2. Comparison of Medical Precedence Terminology [22,23]

Air ambulance (rotary wing)/Ground Ambulance	USAF AE
Priority I, URGENT (evacuate within a maximum of 1 hour)	Priority I, URGENT (evacuated immediately)
Priority IA, URGENT-SURGICAL- (requires far forward surgical intervention to save life and stabilize for further evacuation)	
Priority II, PRIORITY (evacuate within 4 hours or will become URGENT)	Priority II, PRIORITY (evacuate within 24 hours)
Priority III, ROUTINE (evacuate within 24 hours).	Priority III, ROUTINE (evacuate within 72 hours)
Priority IV, CONVENIENCE (rather than necessity). US Army priority not used by USAF	
The USAF uses slightly different precedence categories for patient aeromedical evacuation (AE) on fixed wing aircraft.	

MEDICAL DIRECTION

Medical direction is a critically important aspect of ensuring the delivery of an expected capability of care in the out of hospital environment.[24,25,26] While medical direction may be delegated to any physician regardless of specialty, it does require some unique knowledge and skills. Medical direction has traditionally been the responsibility of the unit physician (flight surgeon for example), although most of these providers do not receive additional formalized or structured education or training for this duty.

Medical direction encompasses both online and offline clinical guidance.[24] This CPG defines medical direction as the direct technical authority to determine capability, promulgate medical policy, and most importantly, the authority to enforce the standard of care through quality assurance with local privileging (official designation of ability to perform medical mission not necessarily the hospital version of "credentialing") actions of individual ERC providers. Online medical direction includes both the on-scene medical supervision of providers actively engaged in patient care, as well as real time clinical guidance of providers via telecommunication.[27] Offline medical direction includes protocol development and review, continuing education of prehospital providers, quality improvement activities, and other duties designed to increase the quality of the system but are not related to immediate and direct patient care.[24] Medical direction can occur at many levels. This CPG will focus on the requirements and responsibilities for unit level medical direction and regional medical direction. The primary mission of the medical director is to ensure the commander is effectively advised on the technical requirements of medical evacuation and the transport unit is meeting expected patient care capability and quality.

The commander of the unit assigned to perform medical evacuation should appoint the unit's physician as the medical director. The medical director is responsible for the technical control and supervision of all en route medical activities of the command and should be delegated that authority in writing. This additional duty order should also include the authority to privilege ERC providers within that organization. It should also include delegation of the authority and prerogative to hold in abeyance, to deny, or to immediately but temporarily suspend clinical privileges/practice when there is reasonable cause to doubt the individual's competence to practice or for any other cause affecting the safety of patients or others. The specific intent of the medical director's decision to implement temporary adverse privileging actions should be the safety and well-being of all patients and safeguarding the quality and efficiency of care delivered by the ERC organization. If a unit physician is not available to provide medical direction the unit conducting medical evacuation should coordinate with the supporting medical treatment facility for a shared medical director.

MINIMUM RECOMMENDED QUALIFICATIONS (UNIT MEDICAL DIRECTOR)

1. Duly commissioned officer in the Medical Corps of the Armed Forces of the United States.
2. Knowledge of ERC mission provided by the unit, unit treatment protocols and CPGs, and capabilities of unit's providers.
3. Completion of the Tactical Combat Medical Care or similar course.
4. Completion of the Joint En Route Care Course (if rotary wing unit) or similar course.
5. Medical director and operational medicine training.

DESIRABLE QUALIFICATIONS (UNIT MEDICAL DIRECTOR)

1. Board certification or eligibility in any specialty recognized by American Board of Medical Specialties or American Osteopathic Association or experience in operational medicine.
2. Previous operational medicine assignments.
3. Experience in medical direction for ERC.

RESPONSIBILITIES (UNIT MEDICAL DIRECTOR)

1. **Offline medical direction:**
    a. Chart reviews of all cases personally or through delegation.
    b. Continuous quality improvement/practice improvement activities.
    c. Detailed case reviews on selected cases from chart review protocol variations or high risk low frequency interventions.

d. Protocol development.

e. Develops criteria for types of providers needed to transport patients based on clinical condition.

f. Oversight of education and training of unit medical providers.

g. Notify the next higher level of command surgeon/theater medical director of systemic issues identified.

h. Conduct a quality assurance program and performance improvement program to ensure standardization of care delivered in accordance with regulations or instructions and Service and Combatant Command policies while validating practices and to propose new practices in ERC.

i. Unit privileging, through technical oversight and supervision, ensuring that providers are qualified, current and proficient in their ERC duties and responsibilities.

j. Ensures completion and delivery of patient care reports into the patient record and the Joint Trauma System.

2. Online medical direction:

a. Due to communication and patient care challenges unique to the deployed environment online medical direction may be most effectively done by physicians other than the transporting unit medical director.[27]

b. Priority of online medical direction is:

i. Transferring physician.

ii. Receiving physician.

iii. Transporting unit medical director.

c. Transporting unit medical director is responsible for ensuring providers know who and under what circumstances to call for online medical direction. It is important to plan/discuss whenever possible any anticipated scenarios requiring deviation from established ERC provider protocols with transferring physician to ensure required medical supplies are available during transport.

Medical direction is required at the unit level and also at the regional level (Patient Evacuation Control Center). Medical direction at the regional level is centered on offline medical direction activities. Regional medical direction works continuously to increase the quality of care delivered during intra-theater transport. Regional medical direction may occur at different levels based on the operating environment but will typically be at the level of the joint operations area and lower. The Joint Force Surgeon's office is the doctrinal proponent for intra-theater patient transport and should assign regional medical directors. A best practice is to appoint a consultant at the Combined Joint Task Force level for EMS and ERC. The Joint Force Surgeon's office shall provide regional medical direction unless they delegate this authority to subordinate regional medical directors.

MINIMUM QUALIFICATIONS (REGIONAL MEDICAL DIRECTOR)

1. Board Certification in a specialty recognized by the American Board of Medical Specialties or American Osteopathic Association, and experience in Operational Medicine and/or extensive experience in en route care.
2. Knowledge about the transporting environment and capabilities of units operating in theater.

DESIRABLE QUALIFICATIONS (REGIONAL MEDICAL DIRECTOR)

1. Previous work as a unit medical provider.
2. Board eligible/certified in EMS (vice fellowship training in EMS).

RESPONSIBILITIES (REGIONAL MEDICAL DIRECTOR)

1. In conjunction with medical planners advise the Combatant/Theater Commander on medical common operating picture and allocation of resources for intra-theater transport.
2. Ensure requirements of documentation of intra-theater transport care are done.
3. Assist medical directors operating in theater and ensure that they have the knowledge and skills to perform the job.
4. Provide technical supervision to medical directors in theater.
5. Ensure relevant out of hospital research is supported and accomplished.
6. Ensure information from intra-theater transportation is supplied to the DoD Trauma Registry.

The Committee on En Route Combat Casualty Care of the JTS recommends the development of service-agnostic courses for Medical Corps officers to serve as entry level training for Medical Directors covering the fundamentals for physician leadership in EMS and ERC oversight and direction.

TREATMENT PROTOCOLS

The recognition of the importance of hospital based CPGs prompted the Institute of Medicine to release a report in 2006 recommending the development of an "evidence-based model for pre-hospital care protocol for the treatment, triage, and transport of patients."[28] By using a consistent approach to a particular kind of patient, it is hoped that critical actions will not be missed, less overall errors will occur, and the patient will get the appropriate, evidence based treatment required. A prehospital medical protocol is directive in nature and guides non-physician providers with patient care decisions in the absence of on-scene or online physician direction. Given their limited scope of practice, the providers are generally expected to follow the protocols as written. The use of protocols is already wide spread throughout the civilian ground and air medical transport arena, as well as within the U.S. Army's new critical care flight paramedic program.

A systematic review looking at the effect of evidence-based clinical guidelines on patient outcomes in the Netherlands found that there was a significant improvement in the process and structure of patient care, and a smaller but significant improvement in outcomes.[29] Another retrospective study reviewed patient outcomes after the implementation of a series of evidence based protocols in an intensive care unit. They noted a small but significant decrease in mortality after the protocols were instituted.[30] A pre-hospital related study compared on-line medical direction of EMS personnel by an emergency nurse to a protocol based method of medical direction. The study found that there was a small improvement in the appropriateness of treatment decisions and a decrease in on scene time in the protocol based group as compared to the online group.[31]

While there is a limited amount of system based protocol research, there are many examples where the implementation of individual protocols have improved patient outcomes.[32,33]

In addition to guiding patient care, protocols also provide a means for performing quality assurance and developing research.[34] By providing a standardized approach to medical care, any deviations from the protocol can be noted, evaluated, and addressed as needed across the EMS system. When gaps in practice are identified, there is also potential for research into causes and solutions to address them. These protocols require regular review and at minimum annual revision.

DOCUMENTATION OF CARE

- Inter-facility patient transports must be documented on an approved patient care record (PCR).
- JTS approved PCR's include:
  - DD Form 1380 Tactical Combat Casualty Care (TCCC) Care
  - DA 4700 overprint Tactical Evacuation Patient Care Record (JTS approved 20141119)
  - AF IMT 3899 Patient Movement Record (20060819, V1)
  - Medical Rescue Report SAR Form 3-50.1A

The Tactical Evacuation Patient Care Record is primarily used for rotary wing transports from point of injury or inter-facility transfer. The AF IMT 3899 is primarily used for Aeromedical Evacuation, with supplements A through K as indicated for Critical Care Air Transport Team movements. The Medical Rescue Report SAR Form 3-50.1A is required whenever a search or rescue is attempted or accomplished that involves Navy personnel or assets. (NTTP 3-50.1)

When completing the PCR, it is important to ensure that the patient's name on the PCR matches the name entered on arrival to the MTF. In cases where a casualty's name is unknown, the MTF will utilize theater predetermined trauma identities. Transport teams must obtain an ID sticker at the time of handover to the MTF to ensure the correct identity is recorded on the PCR.

The PCR should be completed and delivered to the receiving MTF along with the patient. Completed PCR's and After Action Reviews may be submitted to JTS Prehospital at the following email address: usarmy.jbsa.medcom-aisr.list.jts-prehospital@mail.mil

At the time of handover to the MTF, the ERC team will provide a MIST (Mechanism, Injuries, Vital Signs, and Treatments) report summarizing the care received. The MIST report will be recorded by the receiving team on the DD Form 3019 Resuscitation Record for trauma patients, or in the Emergency Department record for non-trauma patients.

The CoERCCC and JTS recommend the development and implementation of ERC checklists for all phases of ERC that serve as clinical decision support tools. An example is found in Appendix A.

PATIENT TRANSPORT CRITERIA

Patient Preparation

1. **Patient stabilized:** ***as much as practical, if incomplete then High Risk Move (see below)*

- ☐ Injuries controlled
- ☐ Resuscitation complete (see below)
- ☐ Treatments steady, non-critical
- ☐ Deterioration en route prophylaxed

2. Patient packaged: **always do*

- ☐ Trauma identity sticker affixed
- ☐ Documentation ready for SBAR hand-off
- ☐ Lines & tubes anticipated, secured
- ☐ Send-along drugs, fluids/blood, equipment ready
- ☐ Exposure protection: eye-pro, hypothermia prevention, ear-pro
- ☐ Military ID/ passport included
- ☐ Belongings cleared if accompanying

3. En-route level of care selected:

- ☐ ICU-level/non-stabilized/high risk patient = gold standard* team
- ☐ Flight Paramedic (+/- ECCN)

*gold standard = multiperson, intensivist-led, qualified/current/proficient

Resuscitation Goals

1. Heart Rate 50-120 /min
2. SBP >90 mm Hg (MAP >60 mm Hg)
3. SpO2 >90-96%,[1] FiO2 required <50%
4. Temp > 95ºF/35ºC
5. Urine Output > 50 mL/h
6. Hemoglobin > 8.0 g/dL
7. Platelets > 50k/mm³
8. INR < 2.0
9. Base Deficit < 6
10. Lactate < 2.5 mmol/L

High Risk: stabilization or resuscitation incomplete/ ICU-level patient

1. Optimize resuscitation as much as possible.
2. Re-verify patient packaging.
3. Require intensivist-led en route critical care team.
4. Document reason for transport before full resuscitation, and risk mitigation steps
5. Collaborate with (1) en route team's physician, and (2) local medical director

1. *Ginde AA. Strategy to Avoid Excessive Oxygen (SAVE-O2) in Critically Ill Trauma Patients: A Multicenter Cluster-Randomized, Stepped Wedge Trial for Targeted Normoxemia. Scientific Plenary Presentation (MHSRS-23-10446), Military Health System Research Symposium; August 14, 2023.*

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

All transported patients (intratheater, interfacility within theater).

INTENT (EXPECTED OUTCOMES)

1. All patients in population of interest have patient care documented on an approved record form.
2. Casualties requiring mechanical ventilation are transported by an enroute critical care provider (critical care flight paramedic, enroute critical care nurse, critical care physician assistant, or critical care physician).
3. Casualties are assessed for adequacy of resuscitation prior to interfacility transfer. For patients with any of the following parameters: HR < 50 or >120, systolic BP <90, core temperature <35 ℃, SpO2 <90%[36] on supplemental O2, Hct <21, base deficit below -5, or pH < 7.3, documentation indicates the need for transfer prior to restoration of physiology to more normal parameters.
4. Ventilated patients are placed on the transport ventilator, all monitors in place and stabilized for 30 minutes prior to departure from the current role of care to the aircraft and a final check for stability is performed/documented prior to wheels up and departure from that role of care.
5. Ventilated patients will receive lung protective ventilator settings (e.g., tidal volume 6-8 ml/kg) and have ventilator settings documented.
6. A hard copy of the medical record accompanies the patient.

PERFORMANCE / ADHERENCE METRICS

1. Number and percentage of patients in the population of interest with patient care documented on an approved record form.
2. Number and percentage of patients on mechanical ventilation who are transported by an enroute critical care provider (critical care flight paramedic, en route critical care nurse, critical care physician assistant, or critical care physician).
3. Number and percentage of patients in the population of interest who are transported prior to physiologic stabilization (HR < 50 or >120, systolic BP <90, core temperature <35 ℃, SpO2 <90% on supplemental O2, Hct <21, base deficit below -5, or pH < 7.3).
4. Number and percentage of patients on mechanical ventilation who are placed on the transport ventilator, all monitors in place and stabilized for 30 minutes prior to departure from the current role of care to the aircraft.
5. Number and percentage of patients who had a final check for stability performed/documented prior to wheels up and departure from that role of care.
6. Number and percentage of patients on mechanical ventilation who had ventilator settings documented.
7. Number and percentage of patients on mechanical ventilation who had ventilator settings documented and with tidal volume 6-8 mL/kg.
8. Number and percentage of patients who had a hard copy of the medical record that accompanied the patient during interfacility transfer.

DATA SOURCE

- Patient Record
- Department of Defense Trauma Registry

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

APPENDIX A: PATIENT TRANSPORT PREPARATION CHECKLIST

Source: U.S. Army Medevac Critical Care Flight Paramedic Standard Medical Operating Guidelines, FY18 Version, Published Oct 19 2017

PRE-FLIGHT CHECKLIST

(for Critical Care and Post-Surgical Transfers)

Once the decision is made to transfer a patient and an accepting physician has been obtained, the following steps will be taken to prepare the patient for transport:

Initials	Evaluation Steps
	1. Sending location/physician: _____Accepting location/physician:_____ Flight nurse called: name / time: _____
	2. Anesthesia called: intubation if indicated. **ETT secured**/marked
	3. Patient meets criteria for en route critical care transport: risk documented by sending physician **(POST-OPERATIVE and CC INTRAFACILITY TRANSFER, Pre-Transfer Patient Status Requirements)**
	Preparation Steps
	Positioning and Proper Monitoring:
	1. Patient moved to litter (collapsible handles), positioned, padded, strapped, equipment (with necessary attachments) added and secured.
	2. For head-injured patients, a pre-sedation neurologic examination will be performed. GCS and neurological exam documented on the en route care form, suggest placing patient sitting at 30°-45°. (For eye injured patients, fox shield in place. For burn patients, **JTTS burn sheet initiated**.)
	3. Ventilator switched to PMI vent at least 20-30 min prior to flight and set with transfer settings ordered by physician.
	4. IV / IO access verified, patent, and secured.
	5. Arterial line inserted and secured, if indicated. Transducer accessible.
	6. Ventilator tubing checked to be free from obstruction, with $ETCO_2$ and secondary lines attached.
	7. Orogastric or nasogastric tube is inserted (unless contraindicated), placement verified with chest x-ray, and attached to low-intermittent suction.
	8. Chest tubes to water seal/suction (place Heimlich valve for non-atrium chest drainage systems).
	9. Wound vacuum disconnected and stowed.
	10. Foley catheter secured, urine output measured and documented.
	Equipment, Medication, Chart, and Personnel Preparation:
	11. Medications needed for flight prepared and organized.
	12. Flight equipment bag obtained and checked. Backup pulse oximeter readily available.
	13. Complete chart photocopied (including x-ray cd), patient belongings bagged and tagged. Transfer Document, or other theater / unit approved transfer document, has been initiated.
	14. Earplugs and eye protection for patient and flight nurse.
	15. If facility sends medical attendant, attendant must have relevant personal protective equipment. In a combat environment this includes: Uniform, Kevlar, IBA, Weapon, ID Card, and equipment for transport.
	Ventilator Management:
	16. Blood gas (preferably ABG) obtained, 15 min after initial settings and ventilator changes. All efforts will be made to have a documented blood gas within 30 minutes prior to flight time.
	17. Adjust ventilator settings and check O_2 tank for length of flight. Resuscitator bag under patient's head with tubing connected to O_2 source, vent tubing free from obstruction.
	Final Verification:
	18. Transferring Physician, Flight Paramedic, ECCN (or Flight Provider) verbally agrees to flight care plan.
	19. Critical Care Transfer Orders reviewed and signed by transferring physician. **(STANDARD ORDER SET for CRITICAL CARE TRANSFERS)**
	20. Enroute CC Transfer Document with completed preflight and enroute care data handed over to and confirmed by receiving provider / facility. **(CENTCOM Transfer Document)**

APPENDIX B: ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

Invasive Fungal Infection in War Wounds

Provide guidance on the recognition and comprehensive management of invasive fungal infection (IFI) in war wounds.

SUMMARY OF CHANGES

1. Updates to IFI wound epidemiology to include surgical and wound healing outcomes
2. Addition of pan-fungal PCR as a potential rapid molecular diagnostic modality
3. Updates on the use of IV voriconazole in those with impaired renal function
4. Updates on posaconazole administration
5. Addition of isavuconazole as a mold active triazole
6. Addition of tissue sample handling considerations to increase culture yield of fungi (i.e. Mucor)
7. Updated Jul 2021 with the Dakin's half-strength solution

BACKGROUND

Clinically significant infections, including invasive fungal wound infections (IFIs), have occurred in the DoD's wounded warrior patient population since the beginning of the current conflicts in Iraq and Afghanistan. During 2009-2010, a substantial increase in the incidence of IFIs was observed among military personnel with wounds sustained in Afghanistan, corresponding to a greater frequency of improvised explosive device blast injuries sustained while on foot patrol in Helmand and Kandahar provinces.[1-3] Mold contamination of the wounds was associated with regions in southern Afghanistan characterized by lower elevation, warmer temperatures,[4] and followed waterways. Of particular clinical concern was an apparent association between patient outcome and the presence of angioinvasive filamentous fungi (e.g., order Mucorales, Aspergillus species, and Fusarium species) often called "molds."[5,6] In general, IFIs are devastating infections associated with increased mortality, morbidity, limb loss, and prolonged hospitalization for survivors.[2,7-10] In civilian literature, mortality rates have been reported as high as 38%.[5] Among the military population, the crude mortality rate was as high as 8% during the first two years of increased prevalence.[11] Dismounted blast injuries were highly contaminated with debris (e.g., soil, plant matter, and shrapnel) and coinfection with bacteria and other fungi was common.[12-14]

Following recognition of the high number of IFI cases, the Joint Trauma System, in collaboration with the Uniformed Services University of the Health Sciences Infectious Disease Clinical Research Program (IDCRP) Trauma Infectious Disease Outcomes Study (TIDOS), launched an outbreak investigation. Review of the findings demonstrated that the most common mechanistic and clinical factors associated with IFI included dismounted blast injury, above-knee traumatic amputations, extensive perineal/pelvic injury (observed trend, but not statistically significant), and massive packed red blood cell transfusion (≥20 units in the first 24 hours).[1,2] Importantly, all IFI patients had a suspicious wound (i.e. unhealthy appearance), defined as recurrent tissue necrosis following at least two surgical debridements. Additional work on IFI classification emphasizes the temporal relationship between surgical findings and laboratory evidence of IFI. (See Appendix A: Examples of Suspicious Wounds.)[15]

The morbidity associated with IFI in war wounds, which may include significant tissue loss, necessitates early surgical and antifungal treatment of patients identified as high risk. Early and aggressive debridement of devitalized tissue and removal of debris are universally accepted as the most important interventions. Patients frequently require surgical amputations and/or amputation revisions, which include extending to more proximal levels (e.g., transtibial to transfemoral or transfemoral to proximal transfemoral, hip disarticulation, or hemipelvectomy.[16] IFI wounds with order Mucorales and Gram-negative bacterial co-infections were observed to have longer time to wound closure, highlighting the need for antifungal and antibacterial therapy.[14]

Early and aggressive debridement of devitalized tissue and removal of debris are universally accepted as the most important interventions.

The 3 main principles of IFI treatment:

1. Surgical debridement of infected tissue;
2. Minimization of immunosuppression (e.g., avoidance of malnutrition or excessive blood product transfusion); and
3. Utilization of empiric dual antifungal medications (e.g., amphotericin B and a broad-spectrum triazole agent) when there is a strong suspicion of an IFI.[9]

Wounds with IFI require a significantly higher number of surgical (not bedside) debridement compared to other wound infections. There are also more changes in amputation level (e.g., revision of a transfemoral amputation to either a hemipelvectomy or hip disarticulation); longer duration following injury to wound closure; and an increased frequency of return to the operating room after wound closure due to infectious complications or drainage.[12] The role of topical antifungal therapy in the prevention of IFI is not clear, but topical therapies have not been demonstrated to have adverse local or systemic effects.

EVALUATION AND TREATMENT

The most important aspect of evaluation and treatment of war wounds is a high index of suspicion for fungal infection, with the early recognition of unhealthy or suspicious wounds followed by early, aggressive, and repetitive surgical debridement of all devitalized tissue and organic material.

After initial debridement, risk factors for invasive fungal infection will be assessed. Identified risk factors include:

- Dismounted blast injury.
- Above-knee immediate traumatic amputation, or progressive transition from below-knee to through-knee to above-knee amputation.
- Extensive perineal, genitourinary, and/or rectal injury.
- Massive transfusion > 20 units packed red blood cells within 24 hours of injury.
- Extensive deep-partial-thickness or full-thickness burns (note: covered elsewhere).[17]

DIAGNOSIS CRITERIA

Diagnostic criteria for an IFI are:

1. Presence of a traumatic wound(s).
2. Recurrent necrosis following at least two consecutive surgical debridements.
3. Laboratory evidence of fungal infection following at least two surgical debridements (i.e. mold culture positivity and/or histopathology indicating tissue invasion).[9,15] This is usually not available at deployed Role 2 or Role 3 Military Treatment Facilities (MTFs), so clinical suspicion is key to early intervention.
4. Fungal wound infection is often manifested by 'tinctorial' or color changes in a wound; early detection of such changes requires repeated inspection by an experienced clinician.[18]
5. IFIs are often diagnosed through routine histopathological examination of tissue specimens. The evaluation of the performance of periodic acid-Schiff (PAS) and Gomori methenamine silver (GMS) in combat trauma-associated IFI demonstrated that the two stains were 84% concordant with false negative rates of 44% for PAS and 15% for GMS; however, neither stain was significantly superior at identifying fungal elements. Overall, there is no added benefit for increasing diagnostic yield with use of both stains.[19]
6. Where available, pan-fungal PCR, for identification of filamentous fungi evaluation offers promise for rapid identification of IFI which can lead to a more timely and accurate diagnosis.

Compared to histopathology, panfungal PCR was specific (99%), but not as sensitive (63%); however, sensitivity improved to 83% in specimens from sites with angioinvasion.[19]

TOPICAL TREATMENT

Initiate topical antifungal therapy on patients with at least three of the above risk factors above in Evaluation and Treatment.[20,22] There is no clear evidence that any topical treatment improves outcomes; however, Dakin's Solution is commonly used. Dakin's used an irrigation solution, which is how it was originally described for use, is likely beneficial for severe infections, including fungal infections. Use Dakin's solution in lieu of saline irrigations for patients meeting criteria.[23,24]

In terms of wound dressings in patients with concern for IFI, nothing has been definitively proven to improve outcomes, but using a topical antifungal is still conditionally recommended. Options include Dakin's-soaked Kerlix dressings, Silver Nitrate Solution, or honey[20,22-28] VAC (negative pressure wound dressings) are not recommended early in the treatment of IFI, or suspected IFI, because daily trips to the operating room are needed for debridement/washout, diagnostics, and source control.

Use of Dakin's solution in the prevention or treatment of IFI, though widespread and probably superior to saline or dry gauze, is unproven. At the US Army Burn Center, a 0.5% aqueous solution of silver nitrate, rather than Dakin's solution, is the preferred treatment for open wounds at risk of IFI. Established IFIs may be treated with topical Nystatin powder. Topical Silver Nitrate is not always available in the deployed environment.[29]

A standardized operative note for wound description is available and should be used throughout the continuum of care for patients at increased risk for IFI. Utilization of this operative note may facilitate the early detection of sequential wound necrosis , which is the crucial first sign of IFI – Appendix B. Description of Bastion Classification of lower limb injuries is presented in Appendix C. Document on the first page of the Operative Note.

DEBRIDEMENT AND ANTIFUNGAL THERAPY

1. For patients transferred to any Role 3 strategic evacuation hub, risk factors for IFI should be assessed and ongoing resuscitation requirements should be addressed as needed. The patient should undergo surgical examination, wound washout, and debridement (if indicated) within 6-12 hours of arrival. Dakin's wound irrigations and topical antifungal treatments as described above should be initiated/continued.
2. Evacuation should be deferred in patients who are clinically unstable and require debridement / wound care every 6-12 hours. Reassess patient to meet evacuation criteria every 24 hours. The surgeon on call should be contacted to evaluate the patient and their wounds immediately on arrival to the next level of care.
3. Upon arrival to the Role 4 MTF (i.e. regional treatment facility outside of the combat zone, but prior to arrival in the United States), the patient should undergo operative exploration, wound washout, and debridement (as indicated) within 6-12 hours. Obtain histopathology and microbiology specimens on all patients with at least three risk factors for IFI and any with clinical suspicion. Topical antifungal therapy should be continued.
4. Upon arrival to an MTF in the United States, the patient should undergo surgical exploration, wound washout, and debridement within 6-12 hours. Obtain histopathology and microbiology

specimens on all patients with at least three risk factors for IFI and/or who have an unhealthy wound appearance (e.g., tissue necrosis). Topical antifungal dressings may be discontinued at any level of care when the treating surgeon observes healthy granulation, or when histopathology and cultures are negative for fungal infection or colonization.

5. Following the first two debridements in theater, if tissue necrosis is observed in wounds after two consecutive debridements, start broad-spectrum antifungal and antibiotic medications immediately and obtain infectious disease consultation. Liposomal amphotericin B is the primary choice due to its effectiveness against mucormycosis, and its reduced potential to induce nephrotoxicity compared to the non-liposomal formulation.[30] Although voriconazole is ineffective against mucormycosis, it has shown to be an active agent against molds that are resistant to amphotericin B (e.g., *Aspergillus terreus* and *Scedosporium prolificans*).[31]
6. In general, patients with IFI are severely injured, and intravenous formulations of antifungal agents are prescribed due to concern for inadequate gastrointestinal antifungal absorption in the septic patient. As soon as feasible, parameters for monitoring antifungal drug toxicities should be implemented (EKG, renal function and LFTs).
7. When voriconazole is administered intravenously, it requires a solubilizing excipient (i.e. sulfobutyl ether β-cyclodextrin), which may accumulate in patients with impaired renal function. A black box warning has been issued due to adverse effects of the accumulating solute in an animal model. Nevertheless, the effects of elevated sulfobutyl ether β-cyclodextrin are unknown in humans.[32] An IV route of administration of voriconazole did not predict worsening renal dysfunction in a small retrospective study with the caveat that only a few patients received voriconazole for ≥ 7 days.[33] Clinical experience to date has not shown permanent renal impairment with this off-label use of voriconazole in the wounded military population.[34]
8. Posaconazole is another triazole agent that has been found to have a 60-70% response rate as a salvage regimen against mucormycosis when prescribed orally.[35-37] Posaconazole tablets are preferred over oral suspension as there is less variability in absorption. Therapeutic drug monitoring should be used if available to achieve trough concentrations > 1.0 µg/mL.[38] Recently, an intravenous formulation was approved and has shown to be useful.[39]

> The recommended dose of posaconazole (tablet formulation) is 300mg by mouth every 12 hours for 2 doses, then 300mg once daily. A posaconazole trough should be obtained on day 7 of therapy. Note that if other formulations of posaconazole are used, the dosing will be different.
>
> The typical starting dose of voriconazole is 6 mg / kg IV every 12 hours for 2 doses, followed by 4 mg/ kg (the patient's actual body weight should be used for dosing). A voriconazole trough should be obtained on day 4 of therapy. Goal trough is 1 - 1.5 mcg / mL.

9. Dual administration of liposomal amphotericin B and a broad-spectrum triazole is recommended as the first-line antifungal agents. Among triazoles, clinical experience has been primarily with voriconazole. Many of the wounds incurred by combat casualties grow more than one mold.[32] Furthermore, prescribe broad-spectrum antibiotics covering both gram-positive and gram-negative organisms (e.g., vancomycin and meropenem)are prescribed as fungal-infected wounds frequently also have bacterial growth

   Initial studies have shown that combat IFI wound cultures growing order Mucorales will have a second non-Mucorales fungus present 30% of the time. Aspergillus species is more difficult to

grow than order Mucorales but should be suspected and empirically treated initially as it has been shown to be virulent in this patient population.[40] Therefore, dual use of a broad-spectrum triazole and liposomal amphotericin B is suggested for wounds infected with either or both of these fungi. If long-term treatment is required, the antifungal medications should be targeted based on culture results.

10. Isavuconazole is a triazole agent available in IV and oral formulations with mold activity including against mucormycosis. Isavuconazole has not been studied in randomized controlled trials but in one multicenter open-label single-arm study, isavuconazole demonstrated similar efficacy to amphotericin B formulations in an external matched control group.[40]
11. Particular attention should be given to aggressive debridement of non-viable tissue at each debridement procedure. The extent of necrosis and appearance of the wound before and after completion of the operation should be documented in the operative note. Appendix B shows a standardized operative note for wound description to be used for patients at increased risk for IFI. Whenever a significant amount of necrotic tissue is debrided, repeat debridement should be performed in 24 hours or less.

    As aggressive surgical debridement of all necrotic and infected tissue remains the mainstay of treatment for IFI, surgical exploration and debridement should continue at least every 24 hours until cessation of necrosis occurs. Wound coverage and closure should not occur until after the wound is clean, contracting, and granulating.
12. If angioinvasive fungal elements or fungal elements among tissue are reported on histopathology, or if cultures are positive in the setting of recurrent necrosis, initiate (or continue) treatment with systemic antifungal medications. Treatment will require close consultation with infectious disease; however, as a general guideline, stop systemic antifungal medications if the wound remains clean/viable for two weeks and if the patient remains clinically stable. If the patient has a fungal infection in more than one body region (e.g., extremity/pelvis, abdomen, and chest), long-term treatment may be indicated.

BIOPSY AND TISSUE CULTURE IN OR

Biopsy should be done at the time of wound exploration (after initial surgical debridement) once the casualty has been evacuated from the theater of conflict (in theater if patient evacuation is delayed) and repeated on subsequent explorations if there are persistent findings (e.g., sepsis physiology, wound necrosis) raising suspicion for IFI.

1. Tissue samples should be obtained from each lower extremity in patients with bilateral lower extremity amputations. Sample all suspected areas.
2. Other sites sampled should be at the discretion of the operative surgeon.
3. At least one specimen should be taken from the junction of viable and necrotic tissue (the last piece of borderline-viable tissue removed).
4. For each site sampled, two tissue samples will be collected fresh in two separate sterile specimen containers.
    - One specimen (1 cm3) for “rush” histopathological examination
    - One specimen (1 cm3) for fungal and bacterial culture

OR STAFF RESPONSIBILITIES

The histopathology specimen is placed in formalin. It is not necessary to send fresh samples.

Order histopathology and cultures (aerobic, anaerobic, and fungal). Special studies are not routinely done, but may be requested (e.g., mycobacterial and viral).

1. Clearly label specimens. Labels contain the following information:
   - Site (e.g., left lower extremity)
   - Patient's name, date of birth, and hospital identification number
   - Date and time obtained
   - "Rush" sticker if available
   - Initials of the person labelling the container
2. Directly contact the on-call pathologist to let them know they will receive a "rush" histopathology specimen for IFI shortly. Deliver the histopathology specimen to the pathology lab immediately.

PATHOLOGY STAFF RESPONSIBILITIES

Pathology staff will coordinate processing as rapidly as possible (≤ 24 hours).

1. Histopathological specimen will be stained with hematoxylin and eosin (H&E) and GMS/PAS stains and evaluated for (1) presence of fungal elements; (2) presence of fungal elements in viable or non-viable tissue; (3) presence of angioinvasion.
2. Microbiological specimen will be cultured for aerobes, anaerobes, and fungi.
3. Mycobacterial and/or viral cultures will not be done routinely under this protocol but may be done with special request.

NOTE:
Fungus can take up to six weeks to grow in culture medium. Therefore, it is recommended that the cultures be checked frequently for two weeks; then once a week for four additional weeks before they are considered final. In addition, wounds without recurrent tissue necrosis may have mold colonization and not a true infection.[41]
Tissue preparation for culturing typically destroys the ribbon-like hyphal elements of fungi belonging to the order Mucorales, reducing growth. The microbiology laboratory should be notified that an IFI is suspected so samples are handled appropriately to maximize culture yield.

PERFORMANCE IMPROVEMENT (PI) MONITORING

POPULATION OF INTEREST

- Identify patients with IFI
- Patients with 3 or more risk factors for invasive fungal infection (dismounted blast, above knee amputation, perineal genitourinary or rectal injury, MT> 20 units RBC + WB within 24h of injury.)

INTENT (EXPECTED OUTCOMES)

- Patients with ≥3 IFI risk factors undergo surgical debridement undergo surgical debridement in the OR within 6-12 hours of arrival at Role 3 or 4 MTFs.
- Patients with ≥3 IFI risk factors and wounds concerning for IFI are:
  - taken to the OR at least every 24 hours
  - are started on IV or PO antifungals.
- An operative note for wound debridement includes the extent of necrosis quantified as a percentage of each wound.

PERFORMANCE/ADHERENCE METRICS

- Number and percentage of patients in the population of interest who undergo surgical debridement in the OR within 6-12 hours of arrival at Role 3 or 4 MTFs.
- Number and percentage of patients in the population of interest who have an operative note that quantifies the extent of wound necrosis as a percentage of each wound.

DATA SOURCES

- Patient Record
- Department of Defense Trauma Registry (DoDTR)

SYSTEM REPORTING & FREQUENCY

The above constitutes the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.

The system review and data analysis will be performed by the JTS Chief and the JTS PI Branch.

RESPONSIBILITIES

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

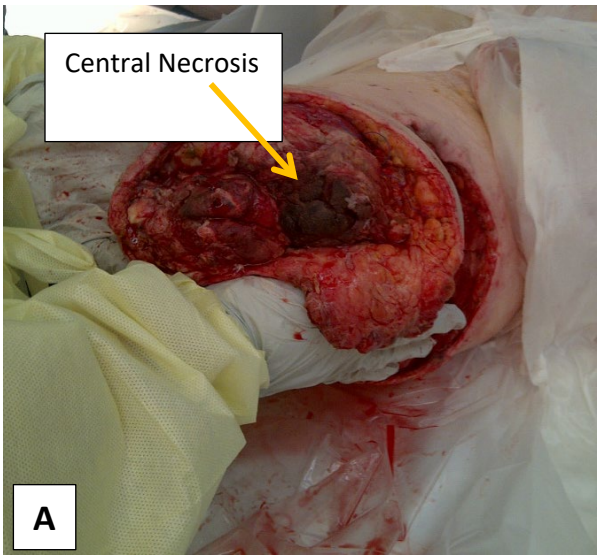
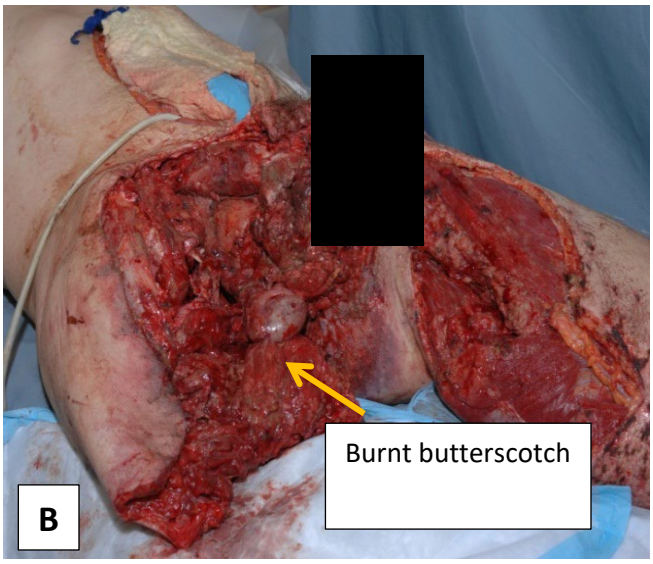
APPENDIX A: EXAMPLES OF SUSPICIOUS WOUNDS

All photos are from different patients.

(A) Patient is 8 days out from injury. His wound is showing central necrosis. Debridement day prior revealed healthy appearing, bleeding tissue.

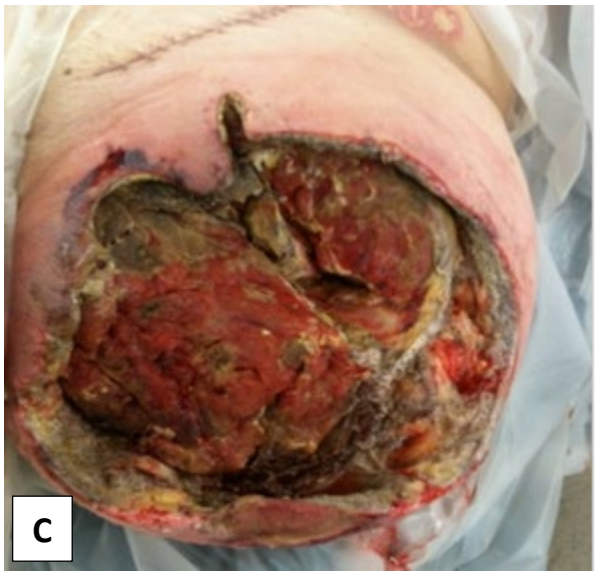
(B) Patient is also 8 days out from injury. Patchy necrosis is seen throughout his right-sided hemipelvectomy. Upon closer inspection, one notices a 'burnt butterscotch' appearance overlying tissue. Anecdotally, this is an additional IFI clinical indicator.

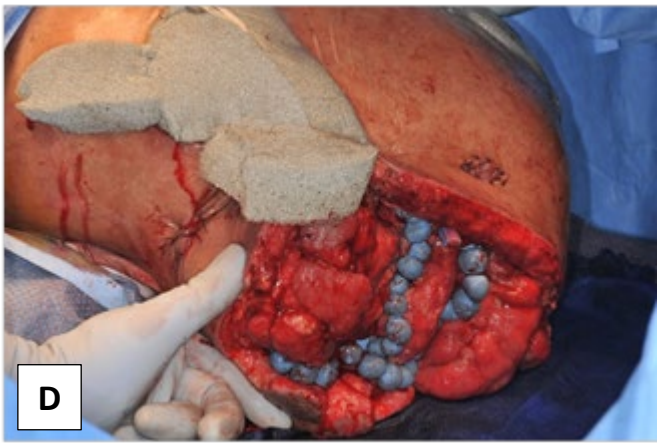




(C) Provides example of tissue necrosis in a previously healthy-appearing wound bed.

(D) Patient is recovering well, but still being treated with anti-microbial beads





(E) Looking closely at the wound, one can see a 'yellow-velvet' covering to the wound. This is indicative of an Aspergillus infection.

APPENDIX C: BASTION CLASSIFICATION OF LOWER LIMB INJURY

BASTION CLASSIFICATION OF LOWER LIMB INJURY CAUSED BY IED. THE MOST PROXIMAL EXTENT.	
Class of limb injury	**Description**
1	Injury confined to foot
2	Injury involving lower leg permitting effective below-knee tourniquet application
3	Injury involving proximal lower leg or thigh, permitting effective above-knee tourniquet application
4	Proximal thigh injury, preventing effective tourniquet application
5	Any injury with buttock involvement

APPENDIX D: INFORMATION REGARDING OFF-LABEL USES IN CPGS

PURPOSE

The purpose of this Appendix is to ensure an understanding of DoD policy and practice regarding inclusion in CPGs of "off-label" uses of U.S. Food and Drug Administration (FDA)–approved products. This applies to off-label uses with patients who are armed forces members.

BACKGROUND

Unapproved (i.e. "off-label") uses of FDA-approved products are extremely common in American medicine and are usually not subject to any special regulations. However, under Federal law, in some circumstances, unapproved uses of approved drugs are subject to FDA regulations governing "investigational new drugs." These circumstances include such uses as part of clinical trials, and in the military context, command required, unapproved uses. Some command requested unapproved uses may also be subject to special regulations.

ADDITIONAL INFORMATION REGARDING OFF-LABEL USES IN CPGS

The inclusion in CPGs of off-label uses is not a clinical trial, nor is it a command request or requirement. Further, it does not imply that the Military Health System requires that use by DoD health care practitioners or considers it to be the "standard of care." Rather, the inclusion in CPGs of off-label uses is to inform the clinical judgment of the responsible health care practitioner by providing information regarding potential risks and benefits of treatment alternatives. The decision is for the clinical judgment of the responsible health care practitioner within the practitioner-patient relationship.

ADDITIONAL PROCEDURES

Balanced Discussion

Consistent with this purpose, CPG discussions of off-label uses specifically state that they are uses not approved by the FDA. Further, such discussions are balanced in the presentation of appropriate clinical study data, including any such data that suggest caution in the use of the product and specifically including any FDA-issued warnings.

Quality Assurance Monitoring

With respect to such off-label uses, DoD procedure is to maintain a regular system of quality assurance monitoring of outcomes and known potential adverse events. For this reason, the importance of accurate clinical records is underscored.

Information to Patients

Good clinical practice includes the provision of appropriate information to patients. Each CPG discussing an unusual off-label use will address the issue of information to patients. When practicable, consideration will be given to including in an appendix an appropriate information sheet for distribution to patients, whether before or after use of the product. Information to patients should address in plain language: a) that the use is not approved by the FDA; b) the reasons why a DoD health care practitioner would decide to use the product for this purpose; and c) the potential risks associated with such use.

JOINT TRAUMA SYSTEM CLINICAL PRACTICE GUIDELINE (JTS CPG)

JTS CPG Development Process (CPG ID:54)

This CPG describes the current processes and procedures for CPG development, periodic review/update, verification, and publication.

APPENDIX E: CPG EDUCATION CONTENT DEVELOPMENT **12**

SUMMARY OF CHANGES

1. The Defense Committee on Trauma (DCoT) will now oversee the CPG process.
2. CPG approval process will start with DCoT Chief, Performance Improvement (PI) Chief and JTS Chief.
3. CPG process has been updated to add the role of the CPG manager who will track and coordinate CPG process with the lead author.
4. Submit CPG topic ideas, corrections, and questions to dha.jbsa.healthcare-ops.list.jts-cpg@health.mil

INTRODUCTION

The JTS CPGs were developed out of necessity to reduce variability in care, improve quality, measure outcomes, and weigh the benefits against the risks and costs of specific interventions. These CPGs provide recommendations to deployed clinicians about the care of trauma patients with specific conditions and are not a substitute for clinical judgment. The CPGs were developed through evidence-based research, systematic review of the literature, PI indicators and input from Subject Matter Experts (SMEs).

BACKGROUND

CPGs are "statements that include recommendations intended to optimize patient care that are informed by a systematic review of evidence and an assessment of the benefits and harms of alternative care options."[1] To date, over 80 CPGs have been instituted to inform the standard of care for the US military in the deployed setting and are reflective of the current "state of the art" at the time of release.

CPGs are developed based on the best available evidence and SME consensus, providing clinicians with recommendations to improve the quality of care, standardization of care and serve as an educational resource while deployed. A systematic and operationally responsive approach to development, verification and implementation of CPGs is taken to ensure rapid field dissemination and provide quality indicators to measure effectiveness. Department of Defense (DoD) trauma cases worldwide are reviewed for CPG compliance by JTS in accordance with PI metrics specified at the end of each CPG.

JTS guidelines may be updated frequently based on operational need and clinical observations and have all been written by SME volunteers. CPGs undergo revisions when the clinical or operational need arises. The JTS CPGs currently do not meet the National Academies of Sciences Engineering and Medicine standards for CPG development[1] to facilitate expediency, responsiveness to the military operational environment and rapid performance improvement. In some cases, there may be little published literature (military or civilian) to guide battlefield or operational medicine, requiring heavy reliance on SME opinion or unpublished analysis of military data. JTS CPGs are timely and reflect evolving threats, technologies, and current realities on the battlefield. The JTS recommends every deploying clinician in their respective Combatant Command (CCMD) who will be providing care for casualties becomes familiar with the CPGs posted on the JTS website.

Strong evidence demonstrates CPG compliance is associated with a reduction in mortality.[2-4] The Donabedian Model for quality improvement in health care states that, besides patient characteristics,

institutional structures and clinical practices determine patient outcome.[5] Evidence-based CPGs are developed to avoid unnecessary variation and promote consistency in healthcare practice throughout the continuum of care to achieve optimal outcomes. JTS CPGs complement the deployed PI process. Since the early days of the U.S. Central Command (USCENTCOM) trauma system, the guidelines have been developed and implemented by clinical SMEs in response to needs identified in the CCMD Area of Operations (AOR). More recently, as the trauma system has matured, the process for identifying, developing, vetting, approving, and implementing CPGs has also matured.

To the greatest extent possible, JTS CPGs are evidence-based. The evidence is derived from the published literature, to include analysis of combat casualty data. When evidence is lacking or unclear, yet a CPG is needed, guidelines are developed based on the best available evidence and SME consensus. In order to ensure CPGs include the latest techniques and innovations, monitoring of all CPGs is essential. To ensure monitoring, each individual CPG will include a system-level PI monitoring plan. Monitoring specifics (e.g., timing, frequency, performance measures) are written in the PI monitoring plan for each CPG. This system-wide monitoring will be conducted by the JTS PI Branch. The PI plan will state the intent and minimum performance measures that will be utilized for monitoring. Trauma directors or their equivalents at the deployed military treatment facility level are expected to implement local PI processes to ensure appropriate adherence to the CPGs; the PI monitoring plan will help guide these efforts. Routine updates to CPGs occur every five years or as the operational need arises or as new evidence surfaces. SMEs include, but are not limited to, military and DoD civilian experts, deployed clinicians, Service specialty consultants, trauma medical directors, trauma program managers, JTS Branch Chiefs, and trauma PI nurse analysts.

Although the JTS CPGs were originally developed for USCENTCOM, they are no longer specific to any particular CCMD or contingency. JTS CPGs are patient-centric guidelines with the intent of keeping the medicine joint and agnostic of Service or location. Because CCMDs greatly differ in climate, terrain, and resources, the JTS CPGs are not representative of a specific CCMD or contingency. Services, unit organizations, and trauma directors may tailor to unit missions, deployed settings, and unique situations.

CPG DEVELOPMENT

TOPIC IDENTIFICATION

Any DoD Service Member can propose a topic for CPG development or revision to the JTS CPG Manager. (See Appendices A-C for process flow charts.) At a minimum, a new CPG topic must include:

- A description of the proposed guideline and perceived gap in care.
- Identification of end-users of the guideline.
- Identification of changes in performance to be driven by the guideline.

TOPIC SELECTION

The JTS clinical leadership (DCoT Chief, DCoT Committee Chairs, PI Chief, and JTS Chief will determine the need for the proposed CPG topic based on:

1. Relevance to the deployed combat casualty environment
2. Potential for reduction of clinically significant variations

3. Incidence, prevalence, or trend identified by DoD Trauma Registry data
4. Evolution of best practices
5. Findings and implementation of lessons learned
6. Requests from theater/CCMD/Service
7. Target audience of CPG (prehospital, en route care, role 2/3)

Submit CPG topic recommendations to: dha.jbsa.healthcare-ops.list.jts-cpg@health.mil

KEY CPG DEVELOPMENT STEPS

Once the proposed CPG topic is approved, DCoT Committee Chair with CPG Manager will initiate the CPG process:

- Identify lead author
- Identify sponsor (generally a DCoT committee will sponsor a CPG)
- Crosswalk with other existing projects/proposals
- Provide literature review/data retrieval support as needed

CPG CONTENT REQUIREMENTS

At a minimum the CPG must contain the following:

- Summary of changes if CPG update
- Background and/or introduction
- Evaluation
- Treatment
- PI metrics (provided by PI team)
- Source references
- Credential information for working group (rank, branch of service, title (MD/DO/RN, etc.)

RESPONSIBILITIES

Title	Responsibility
DCoT Chief	Publish relevant, evidence-based CPGs with best practices.
PI Chief	Monitor global implementation and adherence to CPGs.
JTET Chief	Develop education and training content specific to CPGs.
CCMD / Theater Command Surgeon	Implement and monitor employment of CPGs in AOR.
Trauma Director	• Ensure training, mission-based compliance. • Ensure PI monitoring. • Ensure reporting at the local level.
CPG Manager	• Responsible for overseeing the entire CPG development process from concept to publication • Liaison to lead author • Liaison to PI for metrics • Liaison to DCoT • Oversees socialization of CPGs.
Technical Writer	• Edit and format CPGs. • Routes for approval to JTS Chief/Deputy Chief and DHA PAO. • Publishes CPG on the JTS website. • Uploads CPG to CPG app in JTS Manager.

CPG MANAGER

The CPG Manager will:

1. Cross reference proposals with existing CPGs.
2. Identify way ahead course of actions (COAs)
3. Present COAs to JTS clinical leadership (DCoT Chief, DCoT Committee Chairs, PI Chief, and JTS Chief) for decision.

LEAD AUTHOR

The lead author will:

1. Serve as the point person to the DCoT CPG manager throughout the entire process. (See note below.)
2. Develop an editorial working group comprised of SMEs. A working group ideally will include 5 to 10 experts representing all U.S. military services. Input from civilian and foreign military SMEs is permissible but should not substitute for U.S. tri-service input.
3. Identify and disclose any potential conflicts of interest.
4. Draft CPG structure.
5. Conduct a review of the literature.

6. Define responsibilities and development timeline.
7. Coordinate with the working group.
8. Draft CPG.
9. Coordinate with JTS PI team to establish PI metrics.
10. Identify research, development, test, and evaluation requirements.
11. Submit draft CPG to JTS CPG manager for distribution to reviewers.
12. Collate and reconcile working group and SME input.
13. Prepare final draft of proposed CPG for review.
14. Distribute the CPG proposal to the working group to create the draft CPG.
15. Review available evidence and produce a working draft of the new CPG.
16. Collate and reconcile working group and SME input.

NOTE: The JTS may identify an Academic Action Officer to assist the lead author with literature collection, literature review, and drafting CPG text.

PEER REVIEW & APPROVAL

1. Draft is received from lead author - Chiefs/Chairs will review initial draft.
2. The sponsoring Committee Chair will send the draft to one of the following for review:
   - Specified individual SMEs
   - Select committee
   - DCoT members
3. CPG manager will send draft to select committee for review and vote for approval.
4. CPG manager will send draft to DCoT members for review and vote for approval.
5. DCoT CPG manager will consolidate comments for adjudication by the lead author.
6. After the comments are adjudicated, the CPG will be sent to DCoT Chief in conjunction with PI Chief for approval.
7. The technical writer will route the final draft to the JTS Chief for approval. (The JTS Deputy Chief can sign off on the CPG for publication if the draft has been previously reviewed the Chief.)
8. Upon JTS Chief approval, the technical writer will forward the CPG to DHA for Public Affairs Office/Operations Security (PAO/OPSEC) review and approval. The approved CPG will then be published on the JTS CPG web-based platforms.
   - https://jts.amedd.army.mil/index.cfm/PI_CPGs/cpgs
   - www.deployedmedicine.com
   - Deployed Medicine mobile app

NOTE: Approval authority for implementation of the CPG in any CCMD rests with each CCMD. See Implementation of JTS CPGs below.

REVIEW & UPDATE OF EXISTING JTS CPGS

1. Existing CPGs will be revised at least every five years, or sooner in response to clinical or operational needs. (See Appendix B and Appendix C for process in flow chart.)
2. The JTS PI Branch Chief/DCoT will review each CPG to determine the need for significant revision.
   - If an update is needed, the PI Branch Chief/DCoT will initiate the update by inviting the current CPG's lead author(s) to head the revision process.
   - If the lead author has separated from the military or declines, a new lead author will be identified, and the revision process will follow that of a new CPG.
   - If no update is required as determined by the JTS PI Branch Chief/DCoT, the CPG is submitted to the JTS Chief for re-approval.
3. The JTS PI Branch Chief/DCoT will approve all proposals for rapid/routine updates, clinical enhancements, specific population, and operational considerations to an individual CPG. This approval will create an abbreviated review process for rapid update and will not affect the publication date of the CPG. (See Appendix A-C for detailed processes.) The lead author, and the editorial working group at its discretion, will review these updates for inclusion into the CPG. These updated CPGs will be forwarded to the JTS PI Branch Chief/DCoT Chair(s) for approval before sending to the JTS Chief for final approval.
4. Upon approval, the CPGs will undergo PAO/OPSEC review prior to posting on the JTS CPG webpage and Deployed Medicine.

PUBLICATION & DISSEMINATION

CPGs will be published posting on the JTS website and Deployed Medicine App. The CPG will be socialized through infographics, social media campaigns and though the weekly Combat Casualty Care Conference. See Appendix D for a list of dissemination activities.

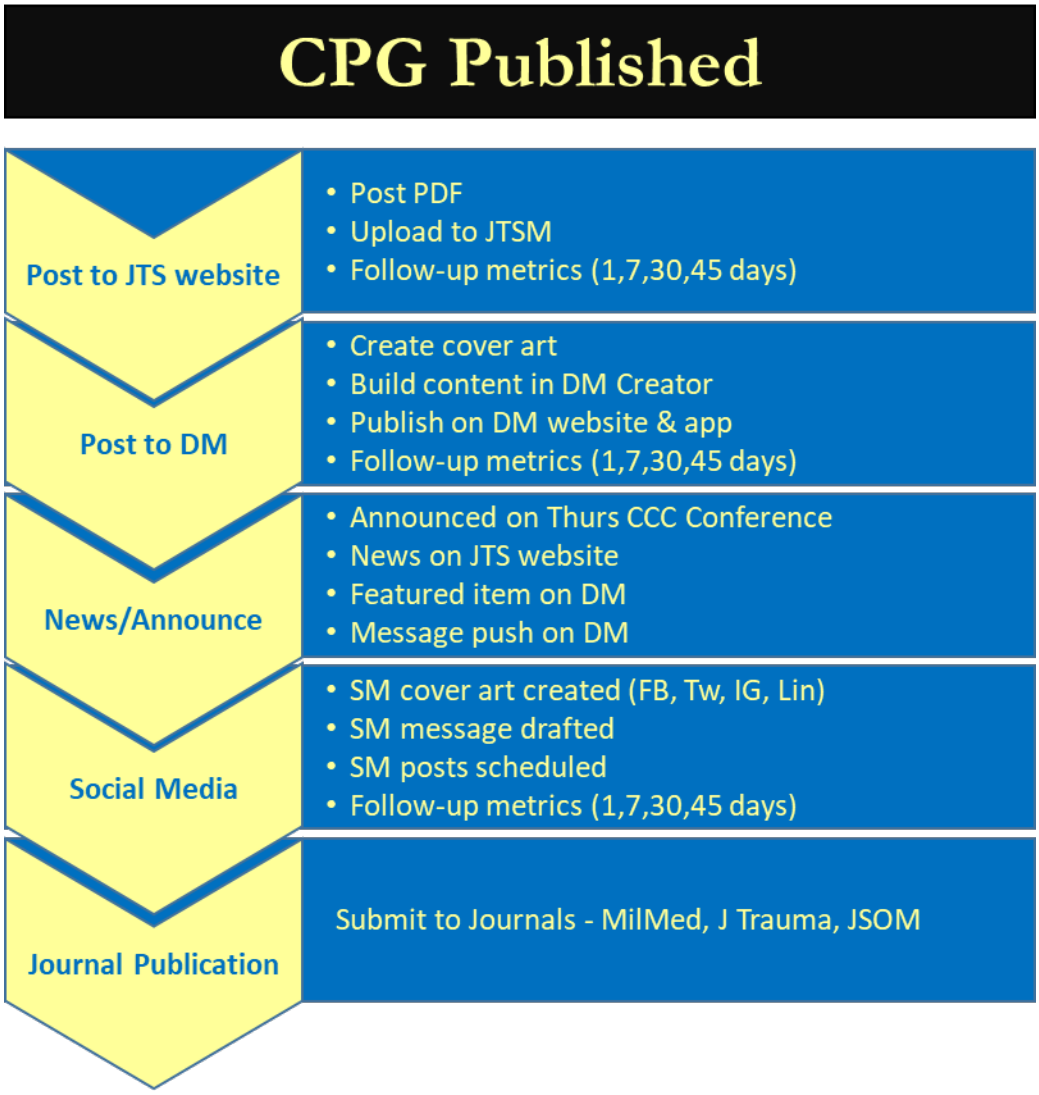
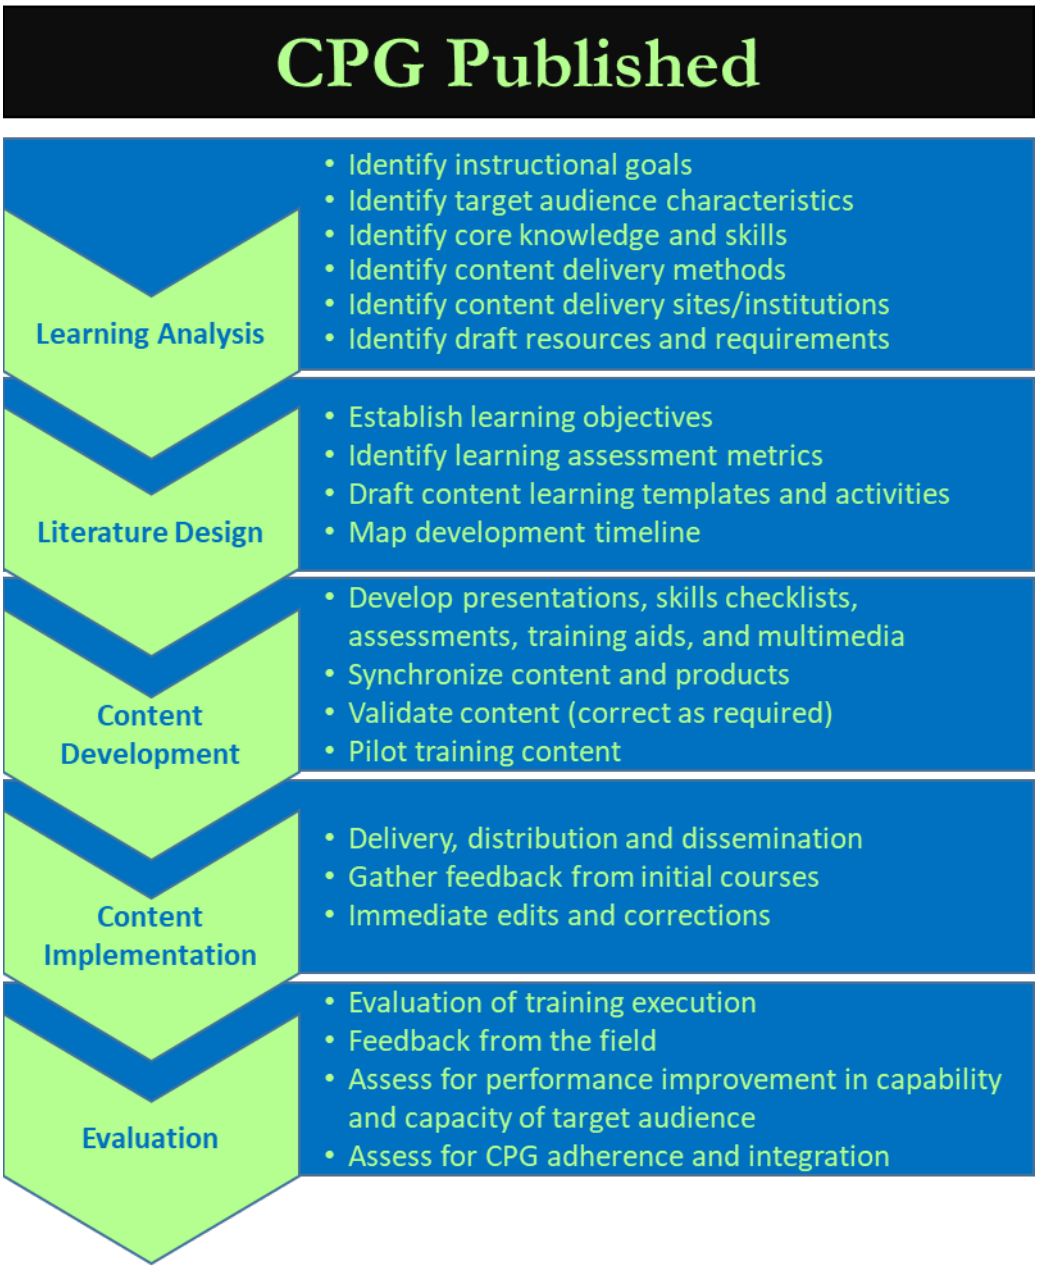
APPENDIX D: CPG DISSEMINATION CAMPAIGN



CPG Published
Post to JTS website
• Post PDF
• Upload to JTSM
• Follow-up metrics (1,7,30,45 days)
Post to DM
• Create cover art
• Build content in DM Creator
• Publish on DM website & app
• Follow-up metrics (1,7,30,45 days)
News/Announce
• Announced on Thurs CCC Conference
• News on JTS website
• Featured item on DM
• Message push on DM
Social Media
• SM cover art created (FB, Tw, IG, Lin)
• SM message drafted
• SM posts scheduled
• Follow-up metrics (1,7,30,45 days)
Journal Publication
Submit to Journals - MilMed, J Trauma, JSOM

APPENDIX E: CPG EDUCATION CONTENT DEVELOPMENT



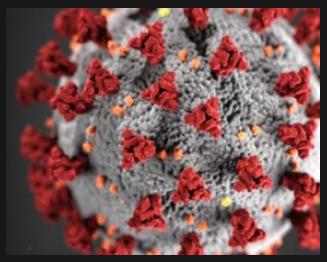
CPG Published
Learning Analysis
• Identify instructional goals
• Identify target audience characteristics
• Identify core knowledge and skills
• Identify content delivery methods
• Identify content delivery sites/institutions
• Identify draft resources and requirements
Literature Design
• Establish learning objectives
• Identify learning assessment metrics
• Draft content learning templates and activities
• Map development timeline
Content Development
• Develop presentations, skills checklists, assessments, training aids, and multimedia
• Synchronize content and products
• Validate content (correct as required)
• Pilot training content
Content Implementation
• Delivery, distribution and dissemination
• Gather feedback from initial courses
• Immediate edits and corrections
Evaluation
• Evaluation of training execution
• Feedback from the field
• Assess for performance improvement in capability and capacity of target audience
• Assess for CPG adherence and integration

Joint Trauma System Clinical Practice Guideline

Special Edition v3.0

Management of COVID-19 in Austere Operational Environments

(Prehospital & Prolonged Field Care), 23 Apr 2021



This practice management guide does not supersede DoD Policy. It is a guideline only and not a substitute for clinical judgment. It is based upon the best information available at the time of publication. It is designed to provide information and assist decision making. It should not be interpreted as prescribing an exclusive course of management. It was developed by experts in this field. Variations in practice will inevitably and appropriately occur when clinicians take into account the needs of individual patients, available resources, and limitations unique to an institution or type of practice. Every healthcare professional making use of this guideline is responsible for evaluating the appropriateness of applying it in the setting of any particular clinical situation.

Intended Scope and Audience

This guideline is intended for the provider operating in an austere, limited resource setting. Providers have varying levels of knowledge, training, and experience in basic critical care concepts. It is not intended to be all inclusive, but to spur further thinking and identify areas where resource limitations or known diseases specify changes to usual practices. The management strategy described is designed for a 24-hour hold of a single critically ill patient and is tailored to the equipment and medications typically available in austere operational settings (Role 1 and Expeditionary Role 2). Refer to the most updated DoD COVID-19 Practice Management Guide for recommended clinical management, and CENTCOM COVID-19 Playbook for operational considerations.

Guiding Principles

1) Our primary mission remains the same. We must maintain the ability to provide damage control resuscitation and surgery in support of combat operations.
2) Prevention of disease transmission to medical personnel is a mission critical consideration for austere teams as there is generally very limited skill redundancy.
3) Primary capability limitations may include manpower, oxygen supply, ventilators, medications, and personal protective equipment (PPE).
4) Care of the critically ill COVID-19 patient is primarily supportive medical care plus appropriate disease transmission precautions.
5) Use of telemedicine to push critical care expertise as far forward as possible should be part of the operational plan.

Key Assumptions

1) Most providers operating in austere locations have equipment geared towards combat casualty care, not necessarily care for patients in severe respiratory failure.
2) Oxygen supply is generally limited to a few portable oxygen tanks and oxygen concentrators not designed to provide high volume oxygen support.
3) Laboratory and radiologic evaluation capabilities are generally limited to non-existent.
4) Local and international supply lines have been significantly affected by COVID-19, with reduced resupply or delivery of disease specific supplies (e.g., testing kits and viral filters).
5) Time to medical evacuation may be significantly prolonged given the global nature of this crisis, lockdown over sovereign airspaces, and the need to limit impact to military air assets.
6) Most austere locations consist of relatively small camps (usually less than 100-300 personnel) with primarily younger, healthier populations. However, some personnel may fall into high risk categories. As such, based upon current epidemiology, planning should account for 1-3 critically ill patients at each austere location.

Key Definitions

1) **Quarantine**: Separation and restriction of movement (ROM) for personnel potentially exposed to a contagious disease but without symptoms of illness. These personnel may have been exposed to a disease and do not know it, or they may have the disease but do not show symptoms. This is a command function that is medically supported.
2) **Isolation**: Separation of sick personnel with a confirmed contagious disease or high index of suspicion (i.e. person under investigation) from people who are not sick. This is a medical function requiring command support.
3) **Person Under Investigation (PUI):** A patient with signs and symptoms consistent with COVID-19 infection and possible exposure to the virus. In areas where COVID-19 is already widespread, symptoms alone may make the diagnosis of "PUI." All PUIs must be isolated.
4) **Contact Spread**: Spread of disease via direct contact with an infected patient or contaminated surface. Contact precautions aim to mitigate this method of transmission.
5) **Droplet Spread**: Spread of disease via relatively large liquid particles that settle from the air, typically within a few feet. Droplet precautions aim to mitigate this method of transmission.
6) **Airborne Spread**: Spread of disease via small liquid particles (aerosols) that remain aloft for prolonged periods of time and may travel longer distances. Airborne precautions aim to mitigate this method of transmission.

Actions on Identification of a COVID-19 PUI

Personal Protective Equipment Considerations

1) The Centers for Disease Control and Prevention (CDC) recommends enhanced droplet precautions. Cover mucosal surfaces (eyes, nose, and mouth) and provide skin contact precautions.
2) N95 masks DO NOT work properly with facial hair; shaving is strongly recommended for anyone participating in direct patient care.
3) Personal Protective Equipment (PPE) should be donned/doffed per CDC instructions and following proper techniques to minimize the risk of self-inoculation.
4) If possible, have a trained observer watch donning and doffing to guard against accidental exposure of medical personnel.
5) The following procedures carry a significantly higher risk of virus aerosol formation:
    a. Tracheal Intubation
    b. Extubation (accidental or planned)
    c. Bag-Valve Mask Ventilation
    d. Any disconnection of the ventilator circuit
    e. Tracheal suctioning without in-line suction device
    f. Tracheostomy (and Cricothyroidotomy)
    g. Cardiopulmonary Resuscitation

Levels of PPE

Levels are based upon risk of disease and risk of procedure.
NOTE: the patient should wear a basic facemask (cloth or otherwise) whenever feasible to provide an additional barrier.

Minimum: Face covering, eye protection glasses, gloves, and makeshift gown.
NOTE: For patients with low probability of disease and where direct contact with the patient is low, gowns may not be required (mirroring conventional droplet precautions).

Better: Surgical mask or N95 mask, face shield (either standalone or with mask) and eye protection, gloves, gown (surgical or contact), head covering.

Best: N95 mask (with or without surgical mask covering) with face shield and disposable head covering or hooded face shield (e.g., Chemical, Biological, Radiological, Nuclear, and high yield Explosives (CBRNE) pro-mask) along with gown and gloves.

Conservation of PPE

1) COVID-19 can survive on various surfaces for up to 72 hours or longer.
2) Use cloth face covering when risk is low to conserve supply of surgical face masks and N95 masks needed for high risk procedures (e.g., endotracheal intubation).
3) Doff PPE in a manner that allows for it to be easily donned again without contacting contaminated surfaces (if possible).

4) For re-use of surgical face masks or N95 masks: while wearing gloves, store the mask in a paper bag in a dry, shaded/indoor area for 72 hours prior to using again. DO NOT use bleach or UV radiation (i.e. sunlight) to 'sterilize' the N95 – this will degrade mask effectiveness.
5) Eye protection glasses and face shields should be cleaned with a diluted bleach solution between uses.

Mask Recommendations

U.S. National Institute for Occupational Safety and Health recommends the following for extended use and re-use of N95 respirators:

1) N95 masks maintain their effectiveness for at least 8 hours of continuous or intermittent use.
2) N95 masks should be discarded following aerosol generating procedures (e.g., endotracheal intubation) or when visibly contaminated with bodily fluids.
3) Consider using a large face shield that sits in front of the mask, wear a surgical mask over-top of the N95, or masking the patient to minimize contamination.
4) Perform hand hygiene with soap and water or an alcohol-based hand sanitizer before and after touching or adjusting the mask.

Quarantine (Asymptomatic Personnel with Identified Exposure)

1) While separate berthing for quarantined individuals is optimal, living space is generally limited in austere settings. As such, berthing with individual rooms should provide adequate protection to allow quarantined individuals to remain in their room.
2) Individuals placed on quarantine per CDC screening guidelines are instructed to stay in their room and conduct self-observation for the development of any symptoms.
3) Teammates should check on the status of the quarantined individual several times daily and bring them food, water, and comfort items as needed.
4) Social distancing is strictly enforced when the individual needs to use the bathroom for toilet and hygiene. They should not use the gym, MWR, or any other common areas while under quarantine.
5) Depending on risk to force and mission requirements, mission critical personnel (including medical personnel) could be allowed to work (face covering, N-95 if possible, otherwise a cloth mask may be used). Early engagement of nonmedical leadership in such decision making is essential.

Isolation (Symptomatic Personnel)

1) ***PUI may not leave isolation*** berthing unless instructed to do so by medical personnel.
2) When outside of the isolation berthing, PUI will be required to wear a cloth face covering and clean hands with soap and water or alcohol based hand sanitizer.
3) No visitors allowed within the isolation berthing.

Initial Medical Evaluation

1) Pre-designate a provider as the COVID provider. This provider should perform all evaluations and procedures to limit exposure to other medical personnel, if possible. Remember, maintaining combat casualty care capability is still the priority. Balance the provider skillset and experience with potential impact on medical support for combat operations. The designated provider may not be the most experienced provider, but can consult with teammates as needed for management, procedures, and nursing care.
2) All patients presenting to sick call with any complaint should be screened for typical COVID-19 symptoms (fever, cough, dyspnea, gastrointestinal complaints) and risk of exposure.
3) If PUI presents to a provider other than the designated COVID attending provider, the patient should be provided a cloth face covering (or surgical mask) and escorted to pre-designated COVID treatment area.
4) If possible, all evaluations and treatment of PUI should be done outside the combat casualty care facility to mitigate potential for contamination of the facility.
5) Medical personnel performing the evaluation should wear the best available PPE (see Appendix B) balancing the supply of PPE with the threat of patient interaction.
6) Examination should include full vital signs including pulse oximetry, work of breathing assessment, pulmonary auscultation, skin temperature, and capillary refill.

Ancillary Tests

Minimum: Rapid Malaria Testing (if febrile in malaria endemic region)

Better (Above +):

- 12-Lead ECG
- Rapid Flu Testing
- Rapid Dengue Testing
- I-STAT arterial blood gas or venous blood gas
- Ultrasound (cardiac and pulmonary)

Best (Above +):

- PA and LAT Chest Films
- Respiratory Pathogen Film Array (i.e. Biofire)
- COVID-19 PCR Testing
- Other laboratory testing listed DoD COVID19 Practice Management Guide

Identifying Patients at Risk for Deterioration:

1) Among patients with mild to moderate symptoms and normal resting pulse oximetry, the risk of deterioration is increased in those presenting with dyspnea, desaturation on exercise testing, and epidemiologic risk factors for severe disease (age over 50, cardiovascular disease, pulmonary disease, immunosuppressive medications). These patients should be monitored closely and considered for early evacuation.

2) Exercise (Walk) Test: Have the patient jog or walk in place for 3 minutes. Inability to complete the test or desaturation below SpO_2 <94% confers a higher risk for clinical deterioration. This is a triage test used by several New York hospitals during the pandemic to help gauge the need for closer monitoring.

Consideration of Alternative Diagnoses

1) If a patient with symptoms possibly consistent with COVID-19 has known risk for or exposure to COVID-19, the patient should be managed as a PUI regardless of the differential diagnosis. This does not mean that alternative and/or comorbid diagnoses are impossible as COVID-19 patients can be co-infected with other pathogens.

2) Life threatening alternative diagnoses (e.g., pulmonary embolism, pneumothorax, acute myocardial infarction, etc.) should always be considered and managed according to standard practices for diagnosis and treatment.

Testing in Austere Locations

1) Most austere locations will be unable to test for COVID-19 using an approved polymerase chain reaction (PCR) assay. However, if testing does become available, the following should be considered:

   - The false negative rate for COVID-19 PCR assay is likely to be significant enough to merit a minimum period of isolation (or quarantine) regardless of test result.
   - Testing priority should be guided by the CDC priority for testing balanced against operational priorities. For example, a patient with mild symptoms and no risk factors for decompensation may not warrant immediate testing. However, if combatant command determines that the individual is mission critical, the testing may be considered a higher priority.

2) Given significant resource constraints in an austere environment (specifically the limited duration of oxygen supply, medication supply, and limited quantity of PPE) coordination for evacuation to the appropriate level of care should be initiated as soon as possible, even if the patient does not necessarily need urgent evacuation as it may take more than 24 hours to execute an evacuation mission. This underscores the importance for early evacuation coordination while simultaneously planning for prolonged care.

3) Appendix A describes a tiered Medical Condition (MedCon) flowchart developed for standardization of terminology across an area of responsibility (AOR) and between medical providers, medical planners, and operational leadership.

Isolation Billeting Location Considerations

1) Most austere locations have group billeting with shared ventilation, making the practice of 'self-isolation' impractical. While individual billeting with separated bathrooms is optimal, patient isolation cohorts may be the best option available with limited space.

2) Billeting should be able to expand to hold multiple patients of varying severity and allow adequate comfort for all patient categories (mild, moderate, and severe illness).

3) Billeting ventilation (i.e. environmental control units) should face away from any gathering areas and common walkways.

4) Billeting entrances should be well marked (e.g., "Isolation Area - No Unauthorized Access!") and include posted guides on proper PPE procedures.

5) Consider location relative to bathrooms and areas traversed to get to the bathrooms. If available, designate bathrooms for isolated patients only. If there is engineering support, a pit toilet can be constructed. Disposable water bottles can be used as urinals.

6) Consider designating a critical care area within or near the isolation area separate from the main medical facility/aid station. Additionally, consider the route that must be traversed in order to transport the patient to an evacuation platform. The focus should be, as much as possible, on preserving the ability to provide combat casualty care, if needed.

7) If confirmatory testing is available, considering cohorting isolated patients by positive test vs. untested or negative test to avoid needlessly infecting PUIs who do not in-fact have COVID-19.

Preparation of Isolation Billeting

1) ***Do not move PUI into isolation billeting before preparation is complete*****.**

2) ***All non-isolated personnel occupying the space must vacate the building*****.**

3) Allow PUI (while wearing a surgical mask) to gather personal belongings from lodging and move into isolation berthing.

   a. Personal hygiene items
   b. Bed sheets and clothing
   c. Electronic devices + chargers

4) If PUI is unable to retrieve items, personnel with mask + gloves (at minimum) should retrieve any essential items.

5) Basic medical items remain in isolation billeting at all times:

   a. Oral thermometer with box of sheaths
   b. Pulse oximeter(s)
   c. Alcohol based hand sanitizer
   d. Stethoscope(s)
   e. Manual blood pressure cuff(s)
   f. Box of surgical masks
   g. 14 day supply of Acetaminophen, ibuprofen and cold/flu medicine as available.

6) PPE Box (for providers, prepositioned outside isolation berthing):

   a. Min 3 gowns (either surgical or yellow contact precaution gowns)
   b. Min 3 N95 masks
   c. Min 6 surgical masks
   d. Min 3 face shields and/or cleaned eyepro
   e. Min 3 surgical caps or bouffant caps
   f. Box of gloves
   g. Tub of disinfectant wipes
   h. Spray bottle of dilute bleach

i. Paper towels (for cleaning)

j. Trash bags

7) Life Support Items

a. Hydration: Water bottles, juice containers, Gatorade, etc.

b. Food: MREs, meal supplement drinks, snacks, etc. Provide hot-meals as able.

c. Hygiene: Box of wet wipes. Encourage use of portable urinals (e.g., empty water bottles). If the bathroom must be shared with non-isolated personnel or if a designated bathroom traverses common areas, the PUI should be escorted by personnel wearing PPE while themselves wearing a mask. The escort will instruct anyone inside the bathroom to vacate prior to use. All surfaces used by the PUI must be cleaned with dilute bleach solution.

d. Trash: Small trash receptacle with bag inside isolation berthing. Large receptacle double bagged will be placed immediately outside the isolation berthing. Biohazard sign will be placed on top. Only medical personnel or designated non-essential/non-high risk personnel will dispose of this trash to minimize risk to others. PUI will be instructed to tie off small bags and place in a large container daily. Consider the local population access to trash and dispose following approved policy for biohazardous waste.

Continued Monitoring Considerations for Personnel in Outpatient Isolation

1) Maintain communication with personnel in isolation. The attending COVID provider will determine the need for more frequent assessments.

2) Once a patient meets MedCon2 criteria or higher, continuous monitoring is recommended as their risk of rapid decompensation rises significantly. (MedCon2: Progressive symptoms that are concerning based upon provider clinical judgment. See Appendix A.)

3) The Prolonged Field Care flowsheet provides a framework for recording frequent assessments and interventions. (See JTS Documentation in Prolonged Field Care CPG.)

4) Consider using video chat (e.g., WhatsApp) to obtain vital signs and perform visual assessment of patient to minimize exposure in MedCon1. (MedCon1: Mild flu-like symptoms, SpO2>94% on room air, hemodynamically normal. See Appendix A.) Patients can take their own pulse oximetry reading and temperature at pre-determined intervals or cohort patients in isolation billeting can do it for each other.

5) If concerning symptoms develop, the COVID attending provider performs an in-person exam using the best available PPE.

Command and Control Considerations

1) Notification of both medical and operational leadership is imperative and should occur soon after identification of a PUI.

2) Official notification in an approved format should be drafted and submitted to the command surgeon (or appropriate designee).

3) If MedCon2 or higher risk category, begin coordination for evacuation to a higher echelon of care as soon as possible.

4) Identify potential close contacts of PUI, screen for symptoms, and manage according to CDC guidelines for high risk exposure.

Performance Improvement Measures

Population of Interest

All hospitalized patients who are COVID-19 positive (includes confirmed and presumptive cases when testing is not available).

Intent (Expected Outcomes)

1) Initial presenting symptoms are documented in the population of interest.
2) Co-morbidities are documented in the population of interest.
3) COVID test sample collection and result times are documented in the population of interest.
4) When intubation is required, staff document levels of use (level 1-surgical mask, level 2-N95, level 3-Powered air-purifying respirator (PAPR)).
5) Recommended treatments for severe and critical COVID-19 patients are received early after hospital admission.

Performance/Adherence Metrics

1) Number and percentage of patients with initial presenting symptoms are documented in the history and physical (H&P) record.
2) Number and percentage of patients with a complete past medical history (PMH) are documented in the H&P.
3) Number and percentage of patients with smoking history are documented in the H&P.
4) Documented number and percentage of patients with COVID test sample collection and result times.
5) Number and percentage of patients requiring intubation procedures who have documentation of level of PPE used by staff (level 1-surgical mask, level 2-N95, level 3-PAPR).
6) Number and percentage of severe and critical patients receiving remdesivir in < 24 hrs and < 48 hrs.
7) Number and percentage of severe and critical patients receiving dexamethasone in < 24 hrs and < 48 hrs.
8) Number and percentage of severe and critical patients receiving COVID convalescent plasma (CCP) in < 24 hrs and < 48 hrs.

Data Source

- Patient Record
- DoDTR

System Reporting & Frequency

- The previous sections constitute the minimum criteria for PI monitoring of this CPG. System reporting will be performed annually; additional PI monitoring and system reporting may be performed as needed.
- The JTS Chief, JTS Program Manager, and the JTS PI Branch will perform the system review and data analysis.

Responsibilities

It is the trauma team leader's responsibility to ensure familiarity, appropriate compliance, and PI monitoring at the local level with this CPG.

Providing Medical Care to a COVID-19 PUI

Oxygen Supply Considerations

(See Appendix F)

1) Take inventory of the equipment and supplies available at your treatment facility. Important items include small oxygen concentrators (SAROS^{TM}), oxygen cylinders (D-cylinders and H-cylinders), and oxygen generating systems (POGS and EDOCS).
2) Identify the closest resource capable of filling oxygen cylinders. This may be a military biomedical maintenance team or host nation industrial gas supply company.
3) If you locate empty oxygen cylinders, begin the process of filling them right away. You will likely consume them quickly if you get a very seriously ill COVID-19 patient.
4) Develop a resupply plan for your oxygen cylinders. A very seriously ill COVID-19 patient will rapidly deplete oxygen supplies.
    - If your facility has the capability to fill oxygen cylinders, then develop a plan to refill tanks. Identify someone not directly involved in patient care since tank refill and patient care may need to occur simultaneously.
    - If your facility does not have the capability to refill oxygen cylinders, then develop a re-supply plan. One option is to coordinate medical cylinder exchange in conjunction with MEDEVAC missions.
5) The SAROS^{TM} oxygen concentrator can provide up to 3 Lpm of 100% O_2. However, when unplugged, battery will only last 30 minutes on continuous flow.
6) SAROSTM can be daisy-chained together to provide higher flow, approximating 5-6 Lpm. A suction Y-connector can be used to connect several together.
7) Ventilators waste less oxygen when using a high pressure hose. A full D-cylinder providing 15 Lpm of O_2 via disposable oxygen tubing will last 20-30 minutes. The same D-cylinder providing 100% FiO_2 through a ventilator connected via green high pressure hosing will last 30-45 minutes (depending on minute ventilation).
8) Reducing minute ventilation (e.g., sedation with or without paralysis) and oxygen consumption (reduce FiO_2 to absolute minimum to attain SpO_2 88-92%) will extend oxygen supplies.

9) If transporting patient(s) to an evacuation pick-up site, anticipate delay and bring double the estimated oxygen supply.

Ventilator Considerations

(See Appendix G, Appendix H and Appendix I)

1) Minimum requirement for an effective ventilator in severe hypoxic respiratory failure:
   a. Must be able to provide Positive End-Expiratory Pressure (PEEP).
   b. Must allow for titration of tidal volume and respiratory rate (control minute ventilation).
   c. Must be able to provide supplemental oxygen greater than room air (>21% FiO_2).
2) Commercial full function ventilators (e.g., Drager, Puritan-Bennett) may be available at some austere locations and are the ideal ventilators to use if available. These ventilators can perform advanced ventilation strategies and are indicated for treatment of COVID patients.
   ***Note**: They are not transport ventilators, as the instruments are sensitive and should remain in an area where they can be protected.* Transfer the patient to a transport vent for evacuation.
3) The Zoll (Impact) EMV+ 731 transport ventilator is available in many military equipment sets and certified to function in all aviation environments. IMPACT 754 ventilators are sufficient, but do not provide Pressure Control - Inverse Ratio Ventilation capability (discussed below).
4) Hamilton T1 transport ventilators provide specialized support options, including advanced pressure control options and integrated high flow oxygen therapy. Certified for ground transport and rotary-wing transport, but not approved for fixed wing aircraft (pressurized cabin) transport.
5) SAVe II rescue ventilators are an option with limited capability: PEEP only up to 10 cm H_2O and minute ventilation only up to 8 Lpm. Oxygen reservoir tubing for the air intake is required to provide supplemental oxygen. If this is the only device available at your location, arrange transfer to a location with more advanced ventilator as soon as possible.
6) SAVe I rescue ventilator has no adjustability and cannot provide PEEP. DO NOT manage critically ill COVID-19 patients with this device. Manual ventilation with a Bag-Valve-Mask (BVM), PEEP valve, and supplemental oxygen will be more effective.

Personnel Considerations

1) Minimize the number of personnel required to care for the PUI. Establish a priority list of who will be available to assist. Ensure that the rest of the team can maintain the combat casualty care capability.
2) In cases where evacuation may be delayed, establish work-rest cycles, allowing for adequate time to hydrate, eat, and sleep. This has been shown to reduce PPE waste, minimize provider exhaustion, and prevent accidental exposures.
3) Ambulatory PUIs ("walking wounded") can potentially assist in monitoring and providing care to more seriously ill patients.
4) Consider having someone (not directly involved in patient care) act as a runner.

Equipment/Supplies

The equipment and supplies needed for the management of a critical ill COVID-19 patient are summarized in Appendix L and Appendix M.

Clinical Care Considerations

Initial reports suggest that among COVID-19 patients who develop critical illness, the rapid decline typically starts about 5-7 days following the first symptoms. Closely monitoring these patients during this time period is critical for early intervention.

Airway Management

1) Minimize viral aerosol formation and direct exposure of medical personnel.
2) Use the best available PPE for high risk procedures like endotracheal intubation. (See Appendix B.)
3) Gauge the need for inserting an advanced airway on the patient work of breathing. COVID-19 patients decompensate rapidly – a low threshold for intubation allows more time for preparation and may prevent complications.
4) If the COVID attending provider does not feel comfortable with placing an advanced airway, consider teleconsultation and/or waiting for arrival of more experienced personnel (e.g., evacuation team). Never try to place an advanced airway unless you know how to do it.
5) One assistant is sufficient during intubation in most cases; however, an additional assistant can be standing by in the "warm" zone at least 2 meters away wearing appropriate PPE.
6) Passively pre-oxygenate with 100% O_2 for at least 5 minutes. Consider placing a surgical mask on the patient (over top of nasal cannula or non-rebreather mask).
7) Utilize strict rapid sequence intubation technique – avoid BVM ventilation if possible. If available, place viral filter in-line during use of BVM.
8) Utilize video laryngoscopy (i.e. GlideScope) if available for intubation to limit direct exposure. If unable to intubate or obtain adequate vocal cord visualization on the first pass, consider the placement of a laryngeal mask airway (LMA) with viral filter. Ventilate with the BVM and PEEP valve until oxygenation is adequate. Then, re-attempt the procedure.
9) Chest X-Ray may not be available or feasible to confirm tube placement. Utilize end-tidal carbon dioxide ($EtCO_2$) monitoring and auscultation to confirm placement.
10) General guide for tube size and depth is as follows: for males use 8.0 endotracheal tube (ETT) inserted to 25cm at the incisors; for females use 7.0 ETT inserted to 23cm at the incisors. In general, place as large an ETT as possible since secretions may be an issue.
11) If available, place heated humidification device (e.g., Hamilton H900) or heat and moisture exchanger (HME) in the INHALATION circuit of the ventilator tubing. If available, place a HEPA filter (microbiological filter) or HME-F (HME plus microbiological filter) in the EXAHALTION circuit of ventilator tubing.

Cricothyroidotomy

Cricothyroidotomy for definitive airway management:

1) Many medics and other providers operating independently in far-forward environments are trained to use cricothyroidotomy as their primary definitive airway. While the use of a surgical airway first line is appropriate in patients presenting in-extremis or with the loss of an airway (e.g., severely injured trauma patients with facial or neck trauma), patients with COVID-19 generally present with gradually progressive symptoms and intact native airways.
2) Early intra-theater transfer to a facility with advanced capabilities is preferable to early cricothyroidotomy whenever possible.
3) Laryngeal mask airway or other supraglottic airway placement may be a sufficient bridge to definitive airway placement. Placement of a mask over the LMA (hole cut in the middle of the mask for the LMA) will minimize aerosol spread from any air leak. PEEP above 10 cm H_2O via LMA may not be effective and may exacerbate any leak around the LMA. Sedation and analgesic requirements for an LMA may be slightly more than with a cricothyroidotomy.
4) Cricothyroidotomy without the ability to provide mechanical ventilation consumes significant resources (manpower required to bag-ventilate the patient with PEEP, inefficient delivery of oxygen via bag-ventilation, and significant aerosol risk to those providing care).

Medication Options

Systemic Corticosteroids

Professional societies recommend using systemic corticosteroids in the treatment of severe and critical COVID-19 (see the DoD COVID-19 PMG for more details). If unfamiliar with corticosteroid treatment regimens, discuss with advanced provider via telehealth prior to initiating therapy.

Antimicrobial Therapy

(to treat possible bacterial pneumonia co-infection)

1) Consider early use of azithromycin (500mg PO or IV daily for a minimum of 5 days) to treat mild to moderate community acquired pneumonia (CAP) in patients with lower respiratory tract symptoms and fever.
2) If azithromycin is not available, doxycycline (100mg PO or IV q12h) can be substituted for empiric treatment of bacterial pneumonia.
3) For patients with severe symptoms, recommend adding ceftriaxone (IV 2gm q24h is the best option) or ampicillin-sulbactam (3gm IV q6hr is a good alternative) or ertapenem (1g IV or IM q24h if it is the only available option).
4) Levofloxacin (750mg PO or IV q24h) is another reasonable option for empiric treatment of severe community-acquired pneumonia.

Fever Management

Fever management with acetaminophen every 6 hours (1000mg IV or 975mg PO or PR) as needed for temperature over 38°C.

Sedation and Analgesia

1) Sedation goal is Richmond Agitation and Sedation Scale (RASS) -1 to -2 (comfortable, transiently responsive to verbal stimulation) and synchronous with the ventilator. Increase sedation and/or

add narcotics to improve patient-ventilator synchrony. Use of paralytics may be required for very severe cases (as discussed below).

2) Ketamine may cause increased secretions which may require more frequent suctioning. If medication options are limited, consider more frequent dosing of midazolam to decrease the dose of ketamine required and potentially decrease the secretion burden.

3) A reference guide for starting and titrating a ketamine drip along with useful adjuncts is provided in JTS Analgesia and Sedation Management during Prolonged Field Care CPG.

4) Combined use of multiple sedatives (i.e. propofol, dexmedetomidine and/or midazolam) may act synergistically to decrease the total sedative dose and help to mitigate the hypotensive effects of propofol, however multiple continuous drips is not recommended outside of an ICU setting. A ketamine drip may be combined with bolus doses of additional medications.

5) *Caution should be used with combining propofol and dexmedetomidine*, especially in younger patients with higher vagal tone due to increased risk of bradycardia and hypotension.

6) Intermittent or doses of fentanyl or hydromorphone may be useful for analgesia and optimizing ventilator synchrony.

7) Low dose vasopressors may be necessary to support hemodynamics in the face of deeper sedation and higher PEEP. (See Appendix D.)

Bronchodilation

1) Use of metered-dose-inhalers (MDIs) over nebulized bronchodilators to treat wheezing will help to minimize risk for infectious aerosol.

2) If the ventilator tubing does not have a capped inlet for medication administration (aka MDI adapter) -- 1) clamp the ETT, 2) disconnect the ventilator, and 3) administer the MDI (6 puffs) directly into the INHALATION circuit. Then, reconnect the ventilator and unclamp ETT to insufflate the medication.

3) Magnesium Sulfate 2gm IV over 20 minutes (similar to treatment of an asthma exacerbation) may be a safer alternative for treatment of bronchospasm given the risks of disconnecting the circuit.

Respiratory Care

Lung-protective ventilation

1) Initiate lung-protective ventilation strategy.
   a. Tidal volume 6mL/kg ideal body weight (IBW)
      - IBW – Men = 50 kg + (2.3 kg x (height in inches - 60))
      - IBW – Women = 45.5 kg + (2.3 kg x (height in inches - 60))
   b. Maintain peak pressure less than 35 mm Hg
   c. Maintain SpO_2 88-95% or PaO_2 55-80 mm Hg
   d. Permit Hypercarbia (but keep arterial pH > 7.30)
   e. Use ARDSnet protocol. (See Appendix E)

2) If ETT must be disconnected from the ventilator for ANY reason, clamp the ETT to prevent decruitment and minimize viral aerosol formation.

3) If in-line suction devices are not available, de-recruitment will likely occur with suctioning. Salvage recruitment maneuvers may be necessary.

4) On the EMV+ 731 (mode AC-V) a recruitment maneuver can be done as follows:

   a. Change upper limit of Peak Inspiratory Pressure (PIP) alarm to 50 cm H_20.
   b. Decrease tidal volume as low as possible (50mL).
   c. Increase PEEP to 30-40 cm H_20.
   d. Hold for 40 seconds (if signs of hemodynamic instability develop, stop the recruitment maneuver, and resume prior settings).
   e. Increase PEEP to 2 cm H_20 ABOVE prior PEEP setting.
   f. Increase tidal volume back to prior setting.
   g. Return upper limit of PIP alarm to prior setting.
   h. Monitor for any persistence of hemodynamic instability or persistently high PIP (Although rare, the high PIP encountered during RMs can cause pneumothorax).

5) Dry Lung. The mantra "a dry lung is a happy lung" still applies in severe COVID-19 care; over resuscitation is likely to be harmful. Fluid resuscitation should be guided by assessment of volume responsiveness. If available and evacuation is significantly delayed, loop diuretics can be used to attain a net even volume status, providing the patient is hemodynamically stable (i.e. not requiring vasopressor support).

Management of Oxygenation

1) Escalate PEEP to 12 cm H_20 as aggressively as possible as hemodynamics allow to optimize oxygenation, minimize FiO_2 needs, and extend oxygen supply.

2) Use the ARDSNet Protocol LOW PEEP table as a guide for further titration of PEEP. Refer to JTS Acute Respiratory Failure CPG.

3) Be prepared to start vasopressors and judicious use of IVF to support pre-load in the face of high PEEP (aka PEEP tamponade).

4) Consider a combination of paralysis and prone positioning early to lengthen duration of available oxygen supply.

5) Consider Inverse Ratio Ventilation (IRV) once patient reaches PEEP 18 cm H_20 on the LOW PEEP table.

Management of Ventilation

1) If blood gas analysis is not available, a general $EtCO_2$ goal of 35 mm Hg +/- 5, is adequate. However, if blood gas analysis is available (i.e. i-STAT), recommend obtaining a baseline PCO_2 and correlate with $EtCO_2$, especially since the gradient between the two is much wider in patients with significant lung disease (i.e. an $EtCO_2$ of 40 may actually represent a PCO_2 of 60 with a pH around 7.24).

2) The manual breath button on the bottom left of EMV+ 731 allows for manual measurement of plateau pressure (Pplat). The Pplat goal is less than 30 cm H_2O with a secondary goal of maintaining

driving pressure (Pplat minus PEEP) below 15 cm H_2O. In the absence of Pplat, a PIP target of less than 35 cm H_20 is also reasonable.

3) If Pplat is greater than 30 cm H_20, decrease set tidal volume by 1 mL/kg steps (about 50-80 mL). Titrate set respiratory rate (RR) up increments of 2 bpm to maintain pH and $EtCO_2$ at goal. Avoid RR above 35 bpm given significant risk for breath stacking and auto PEEP (which will eventually make the patient hemodynamically unstable).

4) If i-STAT with blood gas cartridges are available, consider serial blood gas evaluation (adjusting frequency depending on patient stability).

Reverse Trendelenburg

Reverse Trendelenburg positioning (head of bed up, spine straight) can help offload abdominal pressure contributing to increased thoracic pressure. This can be extremely helpful maneuver to improve pulmonary compliance in obese patients and/or those with intra-abdominal hypertension.

Secretion Management Considerations

1) Increased secretions and mucous plugging of the bronchial tree are extremely common causes for increased oxygen requirement and difficulty with ventilation in patients with severe respiratory failure from lung infections.

2) Anecdotal evidence regarding COVID-19 patients suggests that secretions are problematic in some patients. Additionally, in-line suction (closed system) devices that minimize aerosol formation and de-recruitment are not usually available in austere settings.

3) Heated humidification prevents desiccation (drying out) of secretions and promotes ciliary clearance.

   - Heated-humidification devices are designed to be used along with ventilators (e.g., Hamilton H900).
   - Heat-Moisture Exchangers (HME) are supplies that fit in-line with the ventilator tubing and trap heat and moisture within the circuit.
   - HME Filters (HME-F) are supplies that fit in-line with the ventilator tubing and provide HME and microbiologic filtration.

4) Pharmacologic treatment for secretions generally falls into one of three categories: mucolytics (break up mucous), bronchodilators, or anti-sialagogues (anti-salivation).

   - Mucolytics:
     - Pre-treat with for 10-15 minutes.
     - 20% N-acetylcystine (Mucomyst) as 1-2mL direct instillation into ETT every 6 hours as needed for secretion control.
     - 3% Saline (Hypertonic Saline) as 5mL direct instillation into the ETT every 6 hours as needed for secretion control.
   - Bronchodilators: Albuterol will help dry up secretions. While ultimately decreasing secretion volume, bronchodilators may also increase the risk of a mucous plug formation. Use with caution.
   - Anti-Sialagogues: Has the greatest effect on oral secretions with modest effect on pulmonary secretions (and therefore not routinely recommended for COVID-19 patients). However,

antisialagogues such as scopolamine and glycopyrrolate are often effective at attenuating the increased secretions caused by high dose ketamine.

5) Percussive chest physiotherapy is often provided by respiratory therapists in Role 3 facilities to facilitate secretion clearance. Manual (with hands) or mechanical (with percussive physical therapy devices) can be used to create the same effect.

Adjunctive Strategies for Severe ARDS

1) There is no single right answer as to which strategies should be used in severe ARDS. Each approach may or may not be feasible due to the resource constraints of the austere environment. If unfamiliar with these techniques, obtain teleconsultation.

2) Pressure Control – may include Inverse Ratio Ventilation (PC-IRV):

   a. EMV+ 731 with the most recent software package has the capability to do PC-IRV. While using AC-P mode, PC-IRV is achieved by increasing the Inspiratory-to-Expiratory (I:E) ratio above 1:2 (i.e. 1:1, 2:1, 3:1 and higher).

   b. PC-IRV cannot fully approximate Airway Pressure Release Ventilation (APRV), but is still the best available salvage mode using EMV+ 731.

   c. Once PEEP is maximized (or limited by peak inspiratory pressure) and oxygenation is still not yet at goal, increase the I:E ratio incrementally.

   d. Tidal volume goal remains the same as with conventional ventilation; adjust cycle time (60/RR) to optimize minute ventilation.

   e. Higher I:E ratios are not physiologic, so PC-IRV will likely require increased depth of sedation for patient comfort and synchrony.

3) Paralysis for Patient-Ventilator Synchronization

   a. Adequate depth of sedation is essential prior to starting a paralyzing medication; recommend RASS greater than -2.

   b. SCCM and DoD COVID-19 Practice Management Guide recommend intermittent paralytics over continuous infusions, if possible. Continuous infusion can result in prolonged paralysis if not closely monitored, especially if muscle twitch monitor is not available.

   c. Paralysis with Vecuronium:

      - Bolus: 5mg to 10mg every 60-90 minutes as needed.
      - Infusion: 0.8 to 1.2mcg/kg/min (approx. 80mcg/min for 80kg).
      - Without pump: 40mg vecuronium in 250mL bag (50mL wasted) of normal saline yields 40mg/250mL = 160mcg/mL. For 80mcg/min = 0.5mL/min ~ 1gt every 12 seconds in 10gt tubing.

   d. Monitoring Goal:

      - Absence of muscle movement and no evidence of spontaneous breathing on the ventilator. If possible, titrate to 2/4 TOF (testing device likely only available for surgical teams).
      - Increased HR and BP may suggest inadequate sedation and should be empirically treated by increasing sedation.

- Once the patient is stabilized, consider holding the paralytic at least once every 24 hours to provide for assessment of sedation depth.
- DO NOT hold sedation until paralytic wears off unless absolutely necessary (e.g., sudden hypotension).

4) Prone Positioning
   a. "Awake Self-Proning" with high flow nasal cannula devices has been successfully used in patients with moderate to severe COVID-19 lung disease. If patients are unable to tolerate prone positioning (i.e. strong desire to remain in a tripod position), DO NOT force them into the prone position.
   b. Reference DoD COVID-19 Practice Management Guide for full details on prone positioning precautions and procedures.
   c. Placement of either a central line or additional peripheral access is strongly encouraged PRIOR to prone positioning.
   d. Have push-dose vasopressor medication available during the process of prone positioning and un-positioning, as hypotension frequently occurs.
   e. Proning cycle is generally 16 hours of prone positioning each 24 hours. Match the proning cycle to the daily care plan as much as possible.
   f. Prone positioning may not be feasible or safe during evacuation.

Anticipate Complications

1) Pneumothorax can occur with higher PIP. Sudden increases in PIP and/or hemodynamic instability may indicate pneumothorax.
2) Pneumomediastinum with subcutaneous emphysema can also develop with the use of high PEEP (typically from dissection of air into the adventitia of small bronchi/bronchioles). The development of crepitus across the chest, neck, and/or upper extremities suggests the presence of this condition. Tension physiology from pneumomediastinum is EXCEEDINGLY rare and usually no intervention is needed.
3) Acute kidney injury leading to renal failure is a genuine threat to seriously ill COVID-19 patients. Patients unable to make urine can develop fatal arrhythmias from electrolyte abnormalities and acidotic blood. They need to be evacuated to a location capable of renal replacement therapy as soon as possible.
   a. Oliguria is defined as less than 0.5 mL/kg/hour of urine output (UOP).
   b. Oliguric patients should receive a bolus of 500 cc crystalloid. This may be repeated once if UOP does not improve. If the patient remains oliguric after a 1L bolus, consider the onset of acute tubular necrosis (ATN), especially if UOP remains low for more than 6 hours.
   c. As formal creatinine testing for acute kidney injury (AKI) is not likely to be available, consider urine dipstick testing with attention to specific gravity, proteinuria, and hematuria:
      - An abnormally low (dilute) specific gravity in the setting of oliguria suggests tubular damage and the inability to concentrate urine.
      - Significant proteinuria can be seen in ATN; however, this is not specific and can be seen in a variety of acute medical conditions.

- Hematuria may suggest the presence of myoglobinuria – consider rhabdomyolysis as a cause of acute kidney injury.

d. If UOP suddenly declines or stops, flushing the Foley and/or performing a bladder ultrasound scan can help determine if the problem is mechanical (Foley blockage) or organic (true kidney injury).
